

Embedded polar spaces revisited

Antonio Pasini

Abstract

In this paper we introduce generalized pseudo-quadratic forms and develop some theory for them. Recall that the codomain of a (σ, ε) -quadratic form is the group $\overline{K} := K/K_{\sigma, \varepsilon}$, where K is the underlying division ring of the vector space on which the form is defined and $K_{\sigma, \varepsilon} := \{t - t^{\sigma}\varepsilon\}_{t \in K}$. Generalized pseudo-quadratic forms are defined in the same way as (σ, ε) -quadratic forms but for replacing \overline{K} with a quotient $\overline{K}/\overline{R}$ for a subgroup \overline{R} of \overline{K} such that $\lambda^{\sigma}\overline{R}\lambda = \overline{R}$ for any $\lambda \in K$. In particular, every non-trivial generalized pseudo-quadratic form admits a unique sesquilinearization, characterized by the same property as the sesquilinearization of a pseudo-quadratic form. Moreover, if $q : V \rightarrow \overline{K}/\overline{R}$ is a non-trivial generalized pseudo-quadratic form and $f : V \times V \rightarrow K$ is its sesquilinearization, the points and the lines of $\text{PG}(V)$ where q vanishes form a subspace S_q of the polar space S_f associated to f . After a discussion of quotients and covers of generalized pseudo-quadratic forms we prove the following: let $e : S \rightarrow \text{PG}(V)$ be a projective embedding of a non-degenerate polar space S of rank at least 2; then $e(S)$ is either the polar space S_q associated to a generalized pseudo-quadratic form q or the polar space S_f associated to an alternating form f . By exploiting this theorem we also obtain an elementary proof of the following well known fact: an embedding e as above is dominant if and only if either $e(S) = S_q$ for a pseudo-quadratic form q or $\text{char}(K) \neq 2$ and $e(S) = S_f$ for an alternating form f .

1 Introduction

1.1 Polar spaces and their embeddings

We presume that the reader is familiar with the theory of polar spaces and their projective embeddings. We refer to Tits [7, Chapters 7 and 8] and Buekenhout and Cohen [1, Chapters 7-10] for this topic, but we warn the reader that there are some differences between the setting and the ‘philosophy’ chosen by Tits [7] and the approach of Buekenhout and Cohen [1]. To begin with, the definition of polar space adopted in [1] (which is the same as in Buekenhout and Shult [3]) is more general than that of Tits [7]: a polar space as defined by Tits [7, Chapter 7] is a non-degenerate polar space of finite rank in the sense of [1]. In this paper we shall stick to the definition of [1], according to which a polar space is a point-line geometry $S = (P, L)$ such that for every point $p \in P$ and every line

$l \in L$, the point p is collinear with either all or just one of the points of l . The notion of projective embedding used in [7, Chapter 8] also looks more restrictive than that of [1], although those two notions are in fact equivalent, as we will see in a few lines. According to [1], an embedding of a polar space $S = (P, L)$ is an injective mapping e from the point-set P of S to the set of points of the projective geometry $\text{PG}(V)$ of a vector space V , such that e maps every line of S surjectively onto a line of $\text{PG}(V)$ and $e(P)$ spans $\text{PG}(V)$ (compare our definition of embeddings in Subsection 1.3.3), while Tits [7] also assumes the following:

- (*) The image $e(S) = (e(P), e(L))$ of S by e is a subspace of the polar space S_f associated to a reflexive sesquilinear form $f : V \times V \rightarrow K$.

Needless to say, K is the underlying division ring of V . We warn that in (*) the form f is allowed to be degenerate. As for the definition of subspaces, we refer the reader to Subsection 1.3.1 of this paper.

However, as we said above, these two definitions of embedding are practically the same. Indeed:

Theorem 1.1 [Buekenhout and Cohen [1, Chapter 9]] *Let e be a projective embedding of a polar space S , in the sense of [1] (and of this paper). Suppose that S is non-degenerate of rank at least 2. Then (*) holds for e .*

To my knowledge, the earliest version of Theorem 1.1 that has appeared in the literature is due to Buekenhout and Lefèvre [2]. Only polar spaces of rank 2 are considered by Buekenhout and Lefèvre [2], but their proof also holds for higher rank polar spaces, modulo a few obvious adjustments.

In view of the next theorem, we need a definition. Referring to Subsection 1.3.3 for the definition of quotients and covers of embeddings, we say that a projective embedding of a polar space S is *dominant* if it is not a proper quotient of any other embedding of S . In other words, it is not properly covered by any other embedding. An embedding e of S is *absolutely initial* if all projective embeddings of S are quotients of e . (Both these definitions will be stated again in Subsection 1.3.3, in a more general context.) Clearly, initial embeddings are also dominant.

Theorem 1.2 [Tits [7, 8.6]] *Let S be a non-degenerate polar space of rank at least 2 and let $e : S \rightarrow \text{PG}(V)$ be a projective embedding of S . Let f be as in (*). Then e is dominant if and only if one of the following holds:*

- (1) *The form f is alternating, the underlying field of V has characteristic other than 2 and $e(S) = S_f$.*
- (2) *The image $e(S)$ of S is the polar space S_q associated to a non-singular pseudo-quadratic form q such that f is the sesquilinearization of q .*

Moreover, if e is dominant then it is also absolutely initial, except for two exceptional cases where S has rank 2.

The two exceptional cases mentioned above will be described later in this paper (Section 6, Theorem 6.4).

We now turn to the most important theorem of the theory of polar spaces.

Theorem 1.3 [Tits [7, Chapter 8], Buekenhout and Cohen [1, Chapter 8]] *Let S be a non-degenerate polar space of rank at least 3. Suppose that the planes of S are desarguesian. When S has rank 3 and every line of S belongs to exactly two planes, suppose moreover that the planes of S are Pappian. Then S admits a projective embedding.*

The way to prove Theorem 1.3 is the main difference between [7] and [1]. Tits [7] constructs an embedding of S by a free construction where vector spaces associated to the singular subspaces of S containing a given point of S are amalgamated so that to obtain a vector space \bar{V} which, extended by adding two copies of the underlying division ring K of S , yields a vector space $\tilde{V} = \bar{V} \oplus V(2, K)$ which hosts an embedding \tilde{e} of S . The embedding \tilde{e} constructed in that way is absolutely initial. Explicitly, let \tilde{f} be the reflexive sesquilinear form on \tilde{V} such that \tilde{e} is a subspace of $S_{\tilde{f}}$ (see (*)). If $\tilde{e}(S) = S_{\tilde{f}}$ then \tilde{f} is non-degenerate and \tilde{e} is the unique projective embedding of S . Otherwise, \tilde{f} is the sesquilinearization of a non-singular pseudo-quadratic form \tilde{q} , we have $\tilde{e}(S) = S_{\tilde{q}}$ and all projective embeddings of S arise as quotients of \tilde{e} over a subspace of the radical $\text{Rad}(\tilde{f})$ of \tilde{f} . Thus we also have a complete classification of projective embeddings of non-degenerate polar spaces of rank at least 3.

The proof chosen by Buekenhout and Cohen [1] is different. While Tits's proof is rather algebraic in flavour, the proof by Buekenhout and Cohen is completely geometric. Following the original approach by Veldkamp [8], they prove that the family of hyperplanes of $S = (P, L)$ (see Subsection 1.3.1 for the definition of hyperplanes) forms a projective space, say it $\mathcal{V}(S)$, called the *Veldkamp space* of S . The hyperplanes of S are the points of $\mathcal{V}(S)$ while the lines of $\mathcal{V}(S)$ are families of hyperplanes consisting of all hyperplanes of S containing the intersection of two given hyperplanes. As S is non-degenerate by assumption, for every point $p \in P$ the set of points of S collinear with p is a hyperplane of S , hence a point of $\mathcal{V}(S)$, usually denoted by the symbol p^\perp . Let \hat{e} be the mapping from the point-set of S to the set of points of $\mathcal{V}(S)$ defined by setting $\hat{e}(p) = p^\perp$ for every $p \in P$. Then \hat{e} is an embedding of S in the subspace \hat{V} of $\mathcal{V}(S)$ spanned by $\hat{e}(P)$. We call \hat{e} the *Veldkamp embedding* of S .

In a sense, the Veldkamp embedding \hat{e} is the counterpart of the initial embedding \tilde{e} constructed by Tits. Indeed, while \tilde{e} covers all embeddings of S , the Veldkamp embedding is covered by all of them. In short, \hat{e} is terminal.

Starting with \hat{e} instead of \tilde{e} , in order to classify projective embeddings of polar spaces, we should describe all covers of \hat{e} , or at least the dominant ones, the remaining ones being obtainable as quotients of the latter. However, if we forbid ourselves to exploit the 'only if' part of Tits's Theorem 1.2 (since using that part of that theorem would imply to switching from [1] to [7]), all we can say in general on \hat{e} and its covers is what Theorem 1.1 tells us. According to that theorem, if e is an embedding of S then $e(S)$ is a subspace of S_f for a

suitable reflexive sesquilinear form f , but it can happen that $e(S)$ is a proper subspace of S_f as well as a proper overspace of S_q for every pseudo-quadratic form q admitting f as the sesquilinearization. As a consequence, if \hat{f} is the (σ, ε) -sesquilinear form on \hat{V} such that $\hat{e}(S)$ is a subspace of $S_{\hat{f}}$ (see $(*)$) and \tilde{e} is the initial embedding of S , when $\hat{e}(S) \subset S_{\hat{f}}$ we can only say that $\tilde{e}(S) = S_{\tilde{q}}$ for a suitable (σ, ε) -quadratic form \tilde{q} defined on a suitable subspace \tilde{V} of $\overline{V} \oplus \overline{K}^{\sigma, \varepsilon} / K_{\sigma, \varepsilon}$ (compare Buekenhout and Cohen [1, Theorem 10.12.5]), but we would get in troubles if asked for a more precise description of \tilde{V} valid in general, although we can give such a description in many particular cases.

1.2 Purposes and main result of this paper

The purpose of this paper is to overcome the difficulties discussed at the end of the previous subsection. We will succeed by introducing generalized pseudo-quadratic forms.

We recall that the codomain of a (σ, ε) -quadratic form is the group $\overline{K} := K / K_{\sigma, \varepsilon}$, where K is the underlying division ring of the vector space V on which the form is defined and $K_{\sigma, \varepsilon} := \{t - t^{\sigma} \varepsilon\}_{t \in K}$. *Generalized pseudo-quadratic forms*, to be introduced and discussed in Section 3, are defined in the same way as (σ, ε) -quadratic forms but for replacing \overline{K} with a quotient $\overline{K} / \overline{R}$ for a subgroup \overline{R} of \overline{K} such that $\lambda^{\sigma} \overline{R} \lambda = \overline{R}$ for any $\lambda \in K$. In particular, every generalized pseudo-quadratic form admits a sesquilinearization, characterized by the same property as the sesquilinearization of a pseudo-quadratic form. As we shall prove in Section 3, the sesquilinearization of a non-trivial generalized pseudo-quadratic form is unique. Let $q : V \rightarrow \overline{K} / \overline{R}$ be a non-trivial generalized pseudo-quadratic form and let $f : V \times V \rightarrow K$ be its sesquilinearization. Then the points and the lines of $\text{PG}(V)$ where q vanishes form a subspace S_q of S_f (see Section 3). In Section 5 (Theorems 5.5 and 5.7) we shall obtain the following improvement of Theorem 1.1:

Theorem 1.4 *Let $e : S \rightarrow \text{PG}(V)$ be a projective embedding of a non-degenerate polar space S of rank at least 2. Then $e(S)$ is either the polar space S_q associated to a non-trivial generalized pseudo-quadratic form q or the polar space S_f associated to a non-degenerate alternating form f .*

We recall that the *hull* of an embedding e is the unique dominant embedding that covers e (see Subsection 1.3.3), uniqueness being understood modulo isomorphisms. With e and S as in Theorem 1.4, the hull of e is the initial embedding of S , with the only exception of the two cases of rank 2 mentioned in the last claim of Theorem 1.2.

Let $e(S) = S_f$ for an alternating form f and let \tilde{e} be the hull of e . It is well known that in this case either $\tilde{e} = e$ (when $\text{char}(K) \neq 2$) or $\text{char}(K) = 2$ and $\tilde{e}(S) = S_{\tilde{q}}$ for a non-singular quadratic form $\tilde{q} : \tilde{V} \rightarrow K$, where $\tilde{V} = V \oplus K$, the field K being regarded as a vector field over itself with scalar multiplication $\circ : K \times K \rightarrow K$ defined as follows: $t \circ \lambda = t\lambda^2$ for every vector $t \in K$ and every scalar $\lambda \in K$.

On the other hand, let $e(S) = S_q$ for a generalized pseudo-quadratic form $q : V \rightarrow \overline{K}/\overline{R}$. Let $\circ : \overline{R} \times K \rightarrow K$ be defined as follows: $r \circ \lambda = \lambda^\sigma r \lambda$ for every $r \in \overline{R}$ and every scalar $\lambda \in K$. We will prove in Section 3 that the group \overline{R} equipped with \circ as the scalar multiplication is a K -vector space. (This amounts to say that $\overline{R} \subseteq K^{\sigma, \varepsilon}/K_{\sigma, \varepsilon}$.) Hence we can form a direct sum of K -vector spaces $\tilde{V} = V \oplus \overline{R}$ and, if f is the sesquilinearization of q , we can define a reflexive sesquilinear form $\tilde{f} : \tilde{V} \times \tilde{V} \rightarrow K$ by declaring that $\overline{R} \subseteq \text{Rad}(\tilde{f})$ and \tilde{f} induces f on $V \times V$. As we shall prove in Section 4, a pseudo-quadratic form $\tilde{q} : \tilde{V} \rightarrow \overline{K}$ can be defined on \tilde{V} admitting \tilde{f} as its sesquilinearization and such that the projection $\pi : \tilde{V} \rightarrow \tilde{V}/\overline{R} = V$ induces an isomorphism π_S from $S_{\tilde{q}}$ to S_q . So, the mapping $\tilde{e} := \pi_S^{-1} \cdot e$ is a projective embedding of S and π is a morphism from \tilde{e} to e . Moreover, \tilde{e} is dominant by Theorem 1.2, since $\tilde{e}(S) = S_{\tilde{q}}$ and \tilde{q} is pseudo-quadratic. Therefore:

Theorem 1.5 *The hull of e is the embedding \tilde{e} defined as above.*

Organization of the paper. In the rest of Section 1 we recall some basics on subspaces and embeddings of point-line geometries. In Section 2 we give a summary of the theory of reflexive sesquilinear forms, pseudoquadratic forms and related polar spaces. In Section 3 we introduce generalized pseudo-quadratic forms and develop some theory for them. Quotients and covers of generalized pseudo-quadratic forms are discussed in Section 4. Section 5 is devoted to the proof of Theorem 1.4. Finally, in Section 6 we revisit Theorem 1.2.

1.3 Subspaces and embeddings of point-line geometries

In this subsection we fix some terminology for point-line geometries, focusing on subspaces and projective embeddings.

Throughout this subsection $G = (P, L)$ is a point-line geometry, with P and L as the point-set and the line-set respectively. We regard lines as subsets of P and we assume that no two distinct lines meet in more than one point and every line has at least two points. The *collinearity graph* of G is the graph with P as the vertex-set where two points $a, b \in P$ are declared to be adjacent when they are joined by a line of G . The geometry G is said to be *connected* if its collinearity graph is connected.

Given two point-line geometries $G = (P, L)$ and $G' = (P', L')$, an *isomorphism* from G to G' is a bijective mapping $e : P \rightarrow P'$ such that $\{e(l)\}_{l \in L} = L'$, where for a line $l \in L$ we put $e(l) := \{e(p)\}_{p \in l}$.

1.3.1 Subgeometries and subspaces

A point-line geometry $G' = (P', L')$ is a *subgeometry* of $G = (P, L)$ if $P' \subseteq P$ and for every line $l' \in L'$ there exists a (necessarily unique) line $l \in L$ such that $l' = l \cap P'$. If every line of G' is also a line of G then G' is called a *full* subgeometry of G . On the other hand, if $L' = \{l \cap P' \mid l \in L, |l \cap P'| \geq 2\}$ then G' is called the subgeometry *induced* by G on P' .

A subset $P' \subseteq P$ is called a *subspace* of G if every line of G either is contained in P' or meets P' in at most one point. We say that a geometry $G' = (P', L')$ is a *subspace* of (G, L) if P' is a subspace of G in the previous sense and G' is the subgeometry induced by G on P' . Clearly, subspaces in the latter sense are full subgeometries.

We have mentioned hyperplanes in Subsection 1.1. A *hyperplane* of a point-line geometry $G = (P, L)$ is a proper subspace $H \subset P$ such that every line of G either meets H in a single point or it is fully contained in H .

1.3.2 Notation for vector spaces and projective spaces

In view of the next subsection, it is convenient to fix some notation for vector spaces and related projective spaces. Given a vector space V , we denote by $\text{PG}(V)$ the projective space of 1- and 2-dimensional vector subspaces of V . For a vector $v \in V - \{0\}$, we denote by $[v]$ the projective point of $\text{PG}(V)$ represented by v . If X is a subspace of V we put $[X] = \{[x]\}_{x \in X - \{0\}}$, namely $[X]$ is the subspace of $\text{PG}(V)$ corresponding to X . Given a semilinear mapping $f : V \rightarrow V'$, let $\text{Ker}(f) := f^{-1}(0)$ be the kernel of f . We denote by $\text{PG}(f)$ the mapping induced by f from $\text{PG}(V) - [\text{Ker}(f)]$ to $\text{PG}(V')$.

1.3.3 Projective embeddings

Let $G = (P, L)$ be a connected point-line geometry. A *projective embedding* of G (also called just *embedding* for short) is an isomorphism e from G to a full subgeometry $e(G) = (e(P), e(L))$ of the projective space $\text{PG}(V)$ of a vector space V , such that $e(P)$ spans $\text{PG}(V)$.

We write $e : G \rightarrow \text{PG}(V)$ to mean that e is a projective embedding of G in $\text{PG}(V)$. If K is the underlying division ring of V then we say that e is *defined over K* , also that e is a *K -embedding*, for short. If all projective embeddings of G are defined over the same division ring K then we say that G is *defined over K* and we call K the *underlying division ring* of G .

Given two K -embeddings $e : G \rightarrow \text{PG}(V)$ and $e' : G \rightarrow \text{PG}(V')$, a *morphism* $f : e \rightarrow e'$ is a semilinear mapping $f : V \rightarrow V'$ such that $\text{PG}(f) \cdot e = e'$. As $e'(P)$ spans $\text{PG}(V')$, the mapping f is surjective. If f is bijective then we say that f is an *isomorphism* from e to e' . If a morphism $f : e \rightarrow e'$ exists then we say that e' is a *morphic image* of e (also that e *covers* e') and we write $e \geq e'$. If moreover f is bijective then we write $e \cong e'$ and we say that e and e' are *isomorphic*. If the morphism f is not an isomorphism then we call f a *proper morphism* and we write $e > e'$. Note that, as G is connected by assumption, if $e \geq e'$ then the morphism $f : e \rightarrow e'$ is unique up to isomorphisms.

Let U be a subspace of V such that $e(P) \cap [U] = \emptyset$ and $l \cap [U] = \emptyset$ for any line l of $\text{PG}(V)$ such that $|l \cap e(P)| \geq 2$. Let π_U the projection of V onto V/U . Then the mapping $e_U := \text{PG}(\pi_U) \circ e$ is an embedding of G in $\text{PG}(V/U)$ and π_U is a morphism from e to e_U . We say that U *defines a quotient* of e and we call e_U the *quotient* of e over U .

Clearly, if $f : e \rightarrow e'$ is a morphism then $\text{Ker}(f)$ defines a quotient of e and we have $e' \cong e_U$. By a little abuse, we say that e' is a *quotient* of e , thus taking the word ‘quotient’ as a synonym of ‘morphic image’.

Following Tits [7, Chapter 8] we say that a projective embedding of G is *dominant* if it cannot be obtained as a proper quotient from any other projective embedding of G . If all K -embeddings of G are quotient of a given K -embedding e then we say that e is *K -initial*. If moreover all embeddings of G are quotients of e then e is said to be *absolutely initial*.

Clearly, the K -initial embedding, if it exists, is uniquely determined up to isomorphisms. It can be characterized as the unique dominant K -embedding of G . It is also clear that G admits the absolutely initial embedding if and only if it is defined over some division ring K and admits the K -initial embedding.

Finally, every embedding e of G admits a *hull* \tilde{e} , uniquely determined up to isomorphism by the following property: $\tilde{e} \geq e'$ for every embedding e' of G such that $e' \geq e$. We refer the reader to Ronan [6] for an explicit construction of \tilde{e} . Clearly, the hull \tilde{e} of e is dominant. Up to isomorphisms, it is the unique dominant embedding in the class of the embeddings that cover e . So, if G admits the K -initial embedding and e is defined over K , then \tilde{e} is also K -initial.

The terminology adopted in the previous definitions is essentially the same as in Tits [7], but we warn the reader that different terminologies are also used in the literature. For instance, dominant embeddings and K -initial embeddings are often called *relatively universal* and *absolutely universal* respectively (compare Kasikova and Shult [5]).

2 Preliminaries

In this section we fix some notation to be used throughout this paper and recall a few basics on sesquilinear and pseudo-quadratic forms, taken from Tits [7, Chapter 8] and Buekenhout and Cohen [1, Chapters 7 and 10]. In Section 3, all properties of pseudo-quadratic forms to be recalled in the present section will be rephrased in the setting of generalized pseudo-quadratic forms.

2.1 Admissible pairs

Throughout this paper K is a possibly non-commutative division ring, σ is an anti-automorphism of K and $\varepsilon \in K$ is such that $\varepsilon^\sigma \varepsilon = 1$ and $t^{\sigma^2} = \varepsilon t \varepsilon^{-1}$ for any $t \in K$. Following Buekenhout and Cohen [1, Chapter 10] we call (σ, ε) an *admissible pair* of K . As in Tits [7, Chapter 8], we set

$$K_{\sigma, \varepsilon} := \{t - t^\sigma \varepsilon\}_{t \in K}, \quad K^{\sigma, \varepsilon} = \{t \in K \mid t = -t^\sigma \varepsilon\}.$$

Clearly $K_{\sigma, \varepsilon}$ and $K^{\sigma, \varepsilon}$ are subgroups of the additive group of K . Moreover

$$\lambda^\sigma K_{\sigma, \varepsilon} \lambda = K_{\sigma, \varepsilon} \quad \text{and} \quad \lambda^\sigma K^{\sigma, \varepsilon} \lambda = K^{\sigma, \varepsilon} \quad \text{for every } \lambda \in K - \{0\}, \quad (1)$$

$$K_{\sigma, \varepsilon} \subseteq K^{\sigma, \varepsilon}, \quad (2)$$

$$\left. \begin{aligned} K^{\sigma, \varepsilon} &= K && \text{if and only if } \sigma = \text{id}_K \text{ and } \varepsilon = -1, \\ K_{\sigma, \varepsilon} &= K && \text{if and only if } \sigma = \text{id}_K, \varepsilon = -1 \text{ and } \text{char}(K) \neq 2. \end{aligned} \right\} \quad (3)$$

The quotient group of the additive group of K over $K_{\sigma, \varepsilon}$ is denoted by $K^{(\sigma, \varepsilon)}$ in [7]. In this paper we shall denote it by the symbol \overline{K} :

$$\overline{K} := K^{(\sigma, \varepsilon)} = K/K_{\sigma, \varepsilon}. \quad (4)$$

We will also adopt the following convention. Given $t \in K$ we denote by \bar{t} the element of \overline{K} represented by t :

$$\bar{t} := t + K_{\sigma, \varepsilon}.$$

Accordingly, $\overline{t+s} = t+s + K_{\sigma, \varepsilon}$, $\overline{ts} = ts + K_{\sigma, \varepsilon}$ and $\bar{0}$ is the null element of \overline{K} .

2.1.1 Pairs of trace type

Clearly, if (σ, ε) is an admissible pair of a division ring K then the pair $(\sigma, -\varepsilon)$ is also admissible. So, we can consider the groups $K_{\sigma, -\varepsilon} = \{t + t^\sigma \varepsilon\}_{t \in K}$ and $K^{\sigma, -\varepsilon} = \{t \in K \mid t = t^\sigma \varepsilon\}$. According to (2), $K_{\sigma, -\varepsilon} \subseteq K^{\sigma, -\varepsilon}$. Following Buekenhout and Cohen [1], when $K_{\sigma, -\varepsilon} = K^{\sigma, -\varepsilon}$ we say that the pair (σ, ε) is of *trace type*.

The following is well known (see Tits [7, Chapter 8], also Buekenhout and Cohen [1, Chapter 10]).

Lemma 2.1 *Assume that either $\text{char}(K) \neq 2$ or $\text{char}(K) = 2$ but σ acts non-trivially on the center $Z(K)$ of K . Then, for every element $\varepsilon \in K$ forming an admissible pair with σ , the pair (σ, ε) is of trace type.*

2.1.2 A scalar multiplication in the group \overline{K}

According to (1), $\lambda^\sigma K_{\sigma, \varepsilon} \lambda \subseteq K_{\sigma, \varepsilon}$ for every $\lambda \in K$. Hence can define a scalar multiplication $\circ : \overline{K} \times K \rightarrow \overline{K}$ as follows: $(t + K_{\sigma, \varepsilon}) \circ \lambda = \lambda^\sigma (t + K_{\sigma, \varepsilon}) \lambda = \lambda^\sigma t \lambda + K_{\sigma, \varepsilon}$, namely

$$\bar{t} \circ \lambda = \overline{\lambda^\sigma t \lambda} \text{ for any } \bar{t} \in \overline{K} \text{ and } \lambda \in K. \quad (5)$$

Clearly the following hold for any $\bar{t}, \bar{s} \in \overline{K}$ and $\lambda, \mu \in K$:

$$(\bar{t} \circ \lambda) \circ \mu = \bar{t} \circ (\lambda \mu) \text{ and } (\overline{t+s}) \circ \lambda = \bar{t} \circ \lambda + \bar{s} \circ \lambda. \quad (6)$$

Given an element $\bar{t} \in \overline{K}$ (a subset $\overline{H} \subseteq \overline{K}$) we put $\bar{t} \circ K := \{\bar{t} \circ \lambda\}_{\lambda \in K}$ (respectively $\overline{H} \circ K := \cup_{\bar{t} \in \overline{H}} \bar{t} \circ K$). We say that an element $\bar{t} \in \overline{K}$ is a *o-vector* if

$$\bar{t} \circ (\lambda + \mu) = \bar{t} \circ \lambda + \bar{t} \circ \mu \text{ for any } \lambda, \mu \in K. \quad (7)$$

We denote by \overline{K}° the set of o-vectors of \overline{K} . It is easy to see that $\overline{K}^\circ + \overline{K}^\circ \subseteq \overline{K}^\circ$ and $\overline{K}^\circ \circ K \subseteq \overline{K}^\circ$. Moreover, $\bar{0} \in \overline{K}^\circ$ and $-\overline{K}^\circ = \overline{K}^\circ$. Thus, \overline{K}° can be regarded as a right K -vector space, with \circ taken as the scalar multiplication.

The next lemma is essentially the same as Lemma 10.2.2 of Buekenhout and Cohen [1]. We leave the proof for the reader.

Lemma 2.2 *We have $\overline{K}^\circ = K^{\sigma,\varepsilon}/K_{\sigma,\varepsilon}$.*

The next corollary is well known. (See Tits [7, Chapter 8], also Bruknhout and Cohen [1, Chapter 10], and recall that $\overline{K}^\circ = K^{\sigma,\varepsilon}/K_{\sigma,\varepsilon}$ by Lemma 2.2.)

Corollary 2.3 *Both the following hold.*

- (1) $\overline{K}^\circ = \{\bar{0}\}$ if and only if the pair (σ, ε) is of trace type.
- (2) $\overline{K}^\circ = \overline{K}$ if and only if $K^{\sigma,\varepsilon} = K$.

2.1.3 Closed subgroups of \overline{K}

We say that a subgroup \overline{H} of \overline{K} is *closed* with respect to the scalar multiplication \circ (also \circ -closed or just *closed*, for short) if $\overline{H} \circ K \subseteq \overline{H}$.

Clearly \overline{K} , the vector space \overline{K}° and all of its subspaces are closed subgroups of \overline{K} . We are not going to discuss properties of closed subgroups here. We only mention the following, to be exploited in Section 3.

Let \overline{H} be a closed subgroup of \overline{K} . The scalar multiplication \circ of \overline{K} naturally induces a scalar multiplication on the quotient group $\overline{K}/\overline{H}$, which we shall denote by the same symbol \circ used for the scalar multiplication of \overline{K} . Explicitly,

$$(\bar{t} + \overline{H}) \circ \lambda := \bar{t} \circ \lambda + \overline{H} \quad \text{for every } \bar{t} \in \overline{K}. \quad (8)$$

It is easy to see that this definition is consistent, namely the coset $\bar{t} \circ \lambda + \overline{H}$ does not depend on the choice of the representative \bar{t} of $\bar{t} + \overline{H}$. Moreover, the scalar multiplication defined on $\overline{K}/\overline{H}$ in this way satisfies identities similar to (6).

2.1.4 Proportionality of admissible pairs

Given an admissible pair (σ, ε) of K and a nonzero scalar $\kappa \in K - \{0\}$, let $\varepsilon' := \kappa \kappa^{-\sigma} \varepsilon$ and let σ' be the anti-automorphism of K defined as follows:

$$t^{\sigma'} := \kappa t^\sigma \kappa^{-1} \quad \text{for every } t \in K.$$

All claims gathered in the next lemma are well known (see Tits [7, Chapter 8]):

Lemma 2.4 *The pair (σ', ε') is admissible. Moreover:*

- (1) *We have $\kappa K_{\sigma,\varepsilon} = K_{\sigma',\varepsilon'}$ and $\kappa K^{\sigma,\varepsilon} = K^{\sigma',\varepsilon'}$.*
- (2) *$\kappa \lambda^\sigma t \lambda = \lambda^{\sigma'} \kappa t \lambda$ for any $t \in K$.*

By (1) of Lemma 2.4, left multiplication by κ induces a group isomorphism from $K/K_{\sigma,\varepsilon}$ to $K/K_{\sigma',\varepsilon'}$ as well as from $K^{\sigma,\varepsilon}/K_{\sigma,\varepsilon}$ to $K^{\sigma',\varepsilon'}/K_{\sigma',\varepsilon'}$.

When dealing with two pairs (σ, ε) and (σ', ε') as above it is convenient to keep a record of them in our notation. So we put $\overline{K}^{\sigma,\varepsilon} = K/K_{\sigma,\varepsilon}$, $\overline{K}^{\sigma',\varepsilon'} = K/K_{\sigma',\varepsilon'}$, $\overline{K}^{\circ,\sigma,\varepsilon} = K^{\sigma,\varepsilon}/K_{\sigma,\varepsilon}$, $\overline{K}^{\circ,\sigma',\varepsilon'} = K^{\sigma',\varepsilon'}/K_{\sigma',\varepsilon'}$, $\bar{t}^{\sigma,\varepsilon} = t + K_{\sigma,\varepsilon}$, $\bar{t}^{\sigma',\varepsilon'} =$

$t + K_{\sigma', \varepsilon'}$ and we denote the scalar multiplications of $\overline{K}^{\sigma, \varepsilon}$ and $\overline{K}^{\sigma', \varepsilon'}$ by the symbols \circ_{σ} and $\circ_{\sigma'}$ respectively. This notation is admittedly rather clumsy. We will avoid it as far as possible, but in the present context we need it.

With the above notation, claim (2) of Lemma 2.4 can be rewritten as follows:

$$\kappa(\overline{t}^{\sigma, \varepsilon} \circ_{\sigma} \lambda) = (\kappa(\overline{t}^{\sigma, \varepsilon})) \circ_{\sigma'} \lambda = (\overline{(\kappa t)}^{\sigma', \varepsilon'}) \circ_{\sigma'} \lambda.$$

Thus, left multiplication by κ is an isomorphism of K -vector spaces from $\overline{K}^{\sigma, \varepsilon}$ to $\overline{K}^{\sigma', \varepsilon'}$.

With κ , (σ, ε) and (σ', ε') as above, we write $(\sigma', \varepsilon') = \kappa \cdot (\sigma, \varepsilon)$ and we say that the pairs (σ, ε) and (σ', ε') are *proportional*.

Clearly, if $(\sigma', \varepsilon') = \kappa \cdot (\sigma, \varepsilon)$ then $(\sigma, \varepsilon) = \kappa^{-1} \cdot (\sigma', \varepsilon')$. If moreover $(\sigma'', \varepsilon'') = \kappa' \cdot (\sigma, \varepsilon)$ then $(\sigma'', \varepsilon'') = (\kappa' \kappa) \cdot (\sigma, \varepsilon)$. It is also clear that $\kappa \cdot (\sigma, \varepsilon) = (\sigma, \varepsilon)$ if and only if $\kappa \in Z(K)$ and $\kappa^{\sigma} = \kappa$.

2.2 Reflexive sesquilinear forms

Given a division ring K , a left K -vector space V and an antiautomorphism σ of K , a σ -sesquilinear form is a mapping $f : V \times V \rightarrow K$ such that

$$\begin{aligned} f(x_1 \lambda_1 + x_2 \lambda_2, y_1 \mu_1 + y_2 \mu_2) &= \\ &= \lambda_1^{\sigma} f(x, y_1) \mu_1 + \lambda_1^{\sigma} f(x_1, y_2) \mu_2 + \lambda_2^{\sigma} f(x_2, y_1) \mu_1 + \lambda_2^{\sigma} f(x_2, y_2) \mu_2 \end{aligned} \quad (9)$$

for any $x_1, x_2, y_1, y_2 \in V$ and $\lambda_1, \lambda_2, \mu_1, \mu_2 \in K$. We say that f is *trivial* when $f(x, y) = 0$ for any choice of $x, y \in V$. Obviously, if f is non-trivial then σ is uniquely determined by (9).

A sesquilinear form f is said to be *reflexive* if, for any choice of $x, y \in V$, we have $f(x, y) = 0$ if and only if $f(y, x) = 0$. It is well known (Tits [7, Chapter 8]) that a non-trivial σ -sesquilinear form is reflexive if and only if there exists an element $\varepsilon \in K$ such that

$$f(y, x) = f(x, y)^{\sigma} \varepsilon \quad \text{for any choice of } x, y \in V. \quad (10)$$

If this is the case then (σ, ε) is an admissible pair and f is called a (σ, ε) -sesquilinear form. Clearly, the element ε satisfying (10) is unique.

A *bilinear form* is a σ -sesquilinear form with $\sigma = \text{id}_K$ (whence K is a field, namely it is commutative). A *symmetric bilinear form* is an $(\text{id}_K, 1)$ -sesquilinear form. A bilinear form f is said to be *alternating* if

$$f(x, x) = 0 \quad \text{for any } x \in V. \quad (11)$$

Non-trivial alternating forms are $(\text{id}_K, -1)$ -sesquilinear. Conversely, if K is a field of characteristic $\text{char}(K) \neq 2$ then all $(\text{id}_K, -1)$ -sesquilinear forms are alternating. On the other hand, let $\text{char}(K) = 2$. Then $1 = -1$. In this case a $(\text{id}_K, -1)$ -sesquilinear form is just a symmetric bilinear form. Obviously, not all symmetric bilinear forms satisfy (11).

2.2.1 Orthogonality

Given a (σ, ε) -sesquilinear form $f : V \times V \rightarrow K$, we say that two vectors $x, y \in V$ are *orthogonal* (with respect to f) if $f(x, y) = 0$. If x and y are orthogonal then we write $x \perp y$. Given a vector $x \in V$ we put $x^\perp := \{y \in V \mid y \perp x\}$ and, for a subset $X \subseteq V$, we set $X^\perp := \bigcap_{x \in X} x^\perp$. Clearly x^\perp is either a hyperplane or the whole of V . Hence X^\perp is a subspace of V , for any $X \subseteq V$. Note also that $\langle X \rangle^\perp = X^\perp$. We set

$$\text{Rad}(f) := V^\perp = \{x \in V \mid x^\perp = V\}$$

and we call $\text{Rad}(f)$ the *radical* of f . We say that f is *degenerate* if $\text{Rad}(f) \neq \{0\}$.

A vector $x \in V$ is said to be *isotropic* for f (also *f -isotropic*) if $f(x, x) = 0$, namely $x \in x^\perp$. A subset $X \subseteq V$ is *totally isotropic* for f (*totally f -isotropic*) if $X \subseteq X^\perp$.

Clearly, all vectors of $\text{Rad}(f)$ are isotropic. We say that the form f is *strictly isotropic* if it admits at least one isotropic vector $x \notin \text{Rad}(f)$.

2.2.2 Trace-valued forms

Let $f : V \times V \rightarrow K$ be a (σ, ε) -sesquilinear form. By (10), $f(x, x) \in K^{\sigma, -\varepsilon}$ for every $x \in V$. The form f is said to be *trace-valued* if $f(x, x) \in K_{\sigma, -\varepsilon}$ for every $x \in V$. Two well known characterizations of trace-valued forms are gathered in the next proposition (see Tits [7, Chapter 8], also Buekenhout and Cohen [1, Chapter 10]).

Proposition 2.5 *Let $f : V \times V \rightarrow K$ be a (σ, ε) -sesquilinear form. Then:*

- (1) *The form f is trace-valued if and only if there exists a σ -sesquilinear form $g : V \times V \rightarrow K$ such that $f(x, y) = g(x, y) + g(y, x)^\sigma \varepsilon$ for all $x, y \in V$.*
- (2) *Assume that f is strictly isotropic. Then f is trace-valued if and only if V is spanned by the set of f -isotropic vectors.*

An admissible pair (σ, ε) is of trace type if and only if all (σ, ε) -sesquilinear forms are trace-valued. By Lemma 2.1, when either $\text{char}(K) \neq 2$ or $\text{char}(K) = 2$ but σ acts non-trivially on $Z(K)$, all (σ, ε) -sesquilinear forms are trace-valued.

When K is a field of characteristic 2 the pair $(\text{id}_K, 1)$ is not of trace type. In this case an $(\text{id}_K, 1)$ -sesquilinear form is trace-valued if and only if it is alternating.

2.2.3 The polar space S_f

As in Subsection 1.3.2, given a non-zero vector $x \in V$ we denote by $[x]$ the point of $\text{PG}(V)$ represented by the vector x and, for a subspace X of V , we set $[X] = \{[x] \mid x \in X - \{0\}\}$. We also write $[x_1, x_2, \dots, x_k]$ for $[\langle x_1, x_2, \dots, x_k \rangle]$, for short.

Given a (σ, ε) -sesquilinear form $f : V \times V \rightarrow K$, we say that a point $[x]$ of $\text{PG}(V)$ is *isotropic* for f (also *f -isotropic*) if the vector x is f -isotropic. Similarly,

given a subspace X of V , the subspace $[X]$ of $\text{PG}(V)$ is *totally isotropic* for f (*totally f -isotropic*) if X is totally f -isotropic. We denote by P_f and L_f the set of f -isotropic points and totally f -isotropic lines of $\text{PG}(V)$ and we put $S_f = (P_f, L_f)$.

Assume that $P_f \neq \emptyset \neq L_f$. Then S_f is a polar space (Buekenhout and Cohen [1, Chapter 7]). We call it the polar space *associated to f* . The singular subspaces of S_f are the totally f -isotropic subspaces of $\text{PG}(V)$. The subspace $[\text{Rad}(f)]$ is the radical of S_f . So, S_f is non-degenerate if and only if f is non-degenerate.

The set P_f spans $\text{PG}(V)$ if and only if f is either trivial or trace-valued (Proposition 2.5, claim (2)).

Let $e_f : S_f \rightarrow \text{PG}(V)$ be the inclusion mapping of S_f in $\text{PG}(V)$. If P_f spans $\text{PG}(V)$ then e_f is a projective embedding in the sense of Subsection 1.3.3.

2.2.4 Proportionality of reflexive sesquilinear forms

Let $f : V \times V \rightarrow K$ be a non-trivial (σ, ε) -sesquilinear form and let $\kappa \in K - \{0\}$. It is well known (see e.g. Tits [7, Chapter 8]) that κf is a (σ', ε') -sesquilinear form where $(\sigma', \varepsilon') = \kappa \cdot (\sigma, \varepsilon)$ (notation as in Subsection 2.1.4). We say that f and f' are *proportional*.

Clearly, proportional reflexive sesquilinear forms define the same orthogonality relation. A partial converse of this fact also holds, but in order to state it we need one more definition: the *non-degenerate rank* of a polar space S is the rank of the quotient of S over its radical (Buekenhout and Cohen [1, 7.5.1]). The next proposition is implicit in the theory developed in Chapter 9 of Buekenhout and Cohen [1].

Proposition 2.6 *For $i = 1, 2$, let $(\sigma_i, \varepsilon_i)$ be an admissible pair of K and let $f_i : V \times V \rightarrow K$ be a $(\sigma_i, \varepsilon_i)$ -sesquilinear form. Let $S = (P, L)$ be a full subgeometry of $\text{PG}(V)$, satisfying all the following:*

- (1) *The point-set P of S spans $\text{PG}(V)$.*
- (2) *The geometry S is a polar space with non-degenerate rank at least 2.*
- (3) *The polar space S is a subspace of either of S_{f_1} and S_{f_2} .*

Then the forms f_1 and f_2 are proportional.

Corollary 2.7 *Given $f_1, f_2 : V \times V \rightarrow K$ as in Proposition 2.6, assume that $S_{f_1} = S_{f_2}$ and the polar space $S := S_{f_1} = S_{f_2}$ has non-degenerate rank at least 2. Then f_1 and f_2 are proportional.*

2.3 Pseudo-quadratic forms

Given a division ring K and an admissible pair (σ, ε) of K , let $\overline{K} = K^{(\sigma, \varepsilon)}$, as in (4) of Subsection 2.1. The scalar multiplication \circ is defined as in (5) and, for $t \in K$, we write \bar{t} for $t + K_{\sigma, \varepsilon}$, as in Subsection 2.1.

Let V be a right K -vector space. A (σ, ε) -quadratic form on V is a map $q : V \rightarrow \overline{K}$ such that

- (Q1) $q(x\lambda) = q(x) \circ \lambda$ for any $\lambda \in K$;
- (Q2) there exists a trace-valued (σ, ε) -sesquilinear form $f : V \times V \rightarrow K$ such that $q(x + y) = q(x) + q(y) + f(x, y)$ for any choice of $x, y \in V$.

We call f a *sesquilinearization* of q . Note that in the above definition we allow $\overline{K} = \{\bar{0}\}$ (namely $K_{\sigma, \varepsilon} = K$, equivalently $(\sigma, \varepsilon) = (\text{id}_K, -1)$ and $\text{char}(K) \neq 2$), but we warn that when $\overline{K} = \{\bar{0}\}$ both conditions (Q1) and (Q2) are vacuous. In particular, when $\overline{K} = \{\bar{0}\}$ every trace-valued (σ, ε) -sesquilinear form satisfies (Q2). On the other hand:

Lemma 2.8 *Let $\overline{K} \neq \{\bar{0}\}$. Then q admits a unique sesquilinearization.*

Proof. This lemma is very well known (see Tits [7, Chapter 8], for instance). Nevertheless, it is worth recalling its proof here, as we shall refer to it later, in Section 3, when discussing generalized pseudo-quadratic forms.

let f and f' be sesquilinearizations of q . Then $f(x, y) - f'(x, y) \in K_{\sigma, \varepsilon}$ for any two vectors $x, y \in V$. As $f(x\lambda, y\mu) - f'(x\lambda, y\mu) = \lambda^\sigma(f(x, y) - f'(x, y))\mu$ we also have that

$$\lambda^\sigma(f(x, y) - f'(x, y))\mu \in K_{\sigma, \varepsilon} \text{ for any } \lambda, \mu \in K. \quad (12)$$

If $f(x, y) - f'(x, y) \neq 0$ for some vectors $x, y \in V$ then (12) implies that $K_{\sigma, \varepsilon} = K$. However $K_{\sigma, \varepsilon} \subset K$ by assumption. Hence $f(x, y) = f'(x, y)$ for any $x, y \in V$, namely $f = f'$. \square

In the literature, (σ, ε) -quadratic forms are also called *pseudo-quadratic forms*, keeping the word *quadratic forms* only for $(\text{id}_K, 1)$ -quadratic forms.

We say that a pseudo-quadratic form q is *trivial* if $q(x) = \bar{0}$ for any $x \in V$. Clearly, if $\overline{K} = \{\bar{0}\}$ then q is trivial.

Remark. In the literature, pseudo-quadratic forms are defined only when $\overline{K} \neq \{\bar{0}\}$. However, in the theory of generalized pseudo-quadratic forms, to be exposed in Section 3, we shall allow forms with trivial codomain. Accordingly, we have allowed $\overline{K} = \{\bar{0}\}$ in our definition of pseudo-quadratic forms.

2.3.1 Facilitating forms

Every (σ, ε) -quadratic form q admits a so-called *facilitating form*, namely a σ -sesquilinear form $g : V \times V \rightarrow K$ such that

$$q(x) = \overline{g(x, x)} \text{ for any } x \in V. \quad (13)$$

If $\overline{K} = \bar{0}$ every σ -sesquilinear form is a facilitating form for q . Let $\overline{K} \neq \bar{0}$ and let f be the sesquilinearization of q . Then all facilitating forms of q are obtained as follows (Tits [7, Chapter 8]). Let $(e_i)_{i \in I}$ be a basis of V . Assume that a total

ordering $<$ is given on the index set I . For every $i \in I$ let $g_i \in K$ be such that $q(e_i) = \bar{g}_i$. For any two vectors $x = \sum_{i \in I} e_i \lambda_i$ and $y = \sum_{i \in I} e_i \mu_i$ of V , put

$$g(x, y) := \sum_{i < j} \lambda_i^\sigma f(e_i, e_j) \mu_j + \sum_{i \in I} \lambda_i^\sigma g_i \mu_i. \quad (14)$$

(We warn that all sums occurring in (14) are well defined, since only finitely many of the scalars λ_i and μ_i are different from 0.) Then the mapping g defined as in (14) is a facilitating form for q . Moreover,

$$f(x, y) = g(x, y) + g(y, x)^\sigma \varepsilon \quad \text{for any } x, y \in V. \quad (15)$$

Conversely, given a σ -sesquilinear form $g : V \times V \rightarrow K$ and an element $\varepsilon \in K$ forming an admissible pair with σ , let $q : V \rightarrow \bar{K}$ be defined as in (13). Then q is a (σ, ε) -quadratic form and the form f defined as in (15) is the sesquilinearization of q . Note that f is indeed trace-valued, by claim (1) of Proposition 2.5.

2.3.2 The polar space S_q

Let $q : V \rightarrow \bar{K}$ be a (σ, ε) -quadratic form. We say that a vector $x \in V$ is *singular* for q (also *q-singular*) if $q(x) = \bar{0}$. A subspace $X \subset V$ is said to be *totally singular* for q (also *totally q-singular*) if $q(x) = \bar{0}$ for every $x \in X$.

Clearly, if $q(x) = \bar{0}$ for a vector $x \in V$ then $q(x\lambda) = \bar{0}$ for any $\lambda \in K$. Therefore a point $[x]$ of $\text{PG}(V)$ is totally *q-singular* as a 1-dimensional subspace of V if and only if x is *q-singular*. If this is the case then we say that the point $[x]$ is *singular* for q (also *q-singular*). A subspace $[X]$ of $\text{PG}(V)$ is said to be *totally singular* for q (also *totally q-singular*) if all of its points are *q-singular*. We denote by P_q and L_q the set of *q-singular* points and totally *q-singular* lines of $\text{PG}(V)$ and we put $S_q = (P_q, L_q)$.

Note that P_q or L_q could be empty. The opposite situation, where $S_q = \text{PG}(V)$, occurs when q is trivial, as when $\bar{K} = \bar{0}$.

For the rest of this subsection we assume that $P_q \neq \emptyset \neq L_q$ and $\bar{K} \neq \bar{0}$. We denote by f the sesquilinearization of q .

All propositions to be stated in the rest of this subsection are well known. Their proofs can be found in Tits [7, Chapter 8] and Buekenhout and Cohen [1, Chapter 10]. However we shall recall those proofs here, since in Section 3 we will need them for reference.

Proposition 2.9 *The point-line geometry $S_q = (P_q, L_q)$ is a subspace of the polar space S_f associated to f . Explicitly:*

- (1) $P_q \subseteq P_f$;
- (2) a projective line $[x, y]$ belongs to L_q if and only if $q(x) = q(y) = \bar{0}$ and $f(x, y) = 0$.

Proof. Let $q(x) = \bar{0}$. Then $q(x(\lambda + \mu)) = \bar{0}$ as well, for any choice of scalars $\lambda, \mu \in K$. It follows from (Q2) with x and y replaced by $x\lambda$ and $x\mu$ respectively

that $\lambda^\sigma f(x, x)\mu \in K_{\sigma, \varepsilon}$ for any choice of λ and μ . If $f(x, x) \neq 0$, this forces $K_{\sigma, \varepsilon} = K$, contradicting the assumption that $\overline{K} \neq \overline{0}$. Therefore $f(x, x) = 0$. Claim (1) is proved.

Turning to claim (2), let $[x, y] \in L_q$. Then $q(x\lambda + y\mu) = \overline{0}$ for any choice of $\lambda, \mu \in K$. According to (Q2), this forces $\lambda^\sigma f(x, y)\mu \in K_{\sigma, \varepsilon}$ for all $\lambda, \mu \in K$. Hence $f(x, y) = 0$, since $K_{\sigma, \varepsilon} \subset K$. The ‘only if’ part of (2) is proved. The ‘if’ part is trivial. \square

The next two corollaries immediately follow from Proposition 2.9.

Corollary 2.10 *A subspace $[x_1, x_2, \dots, x_k]$ of $\text{PG}(V)$ is totally q -singular if and only if it is totally isotropic for f and $q(x_1) = q(x_2) = \dots = q(x_k) = \overline{0}$.*

Corollary 2.11 *The point-line geometry S_q is a polar space. Its singular subspaces are the totally q -singular subspaces of $\text{PG}(V)$. The set $P_q \cap [\text{Rad}(f)]$ is the radical of S_q .*

The radical $P_q \cap [\text{Rad}(f)]$ of S_q is a subspace of $[\text{Rad}(f)]$. In other words, the q -singular vectors of $\text{Rad}(f)$ form a subspace of $\text{Rad}(f)$. We call this subspace the *radical* of q and we denote it by the symbol $\text{Rad}(q)$. Following Buekenhout and Cohen [1, Chapter 10] we call $\text{Rad}(f)$ the *defect* of q (but we warn that this word is used with a different meaning in Tits [7]).

The form q is said to be *singular* (also *degenerate*) if $\text{Rad}(q) \neq \{0\}$.

Proposition 2.12 *If $P_q \not\subseteq [\text{Rad}(f)]$ then P_q spans $\text{PG}(V)$.*

Proof. Suppose that $P_q \not\subseteq [\text{Rad}(f)]$. Then there exists a q -singular point $[a] \notin [\text{Rad}(f)]$. As $a \notin \text{Rad}(f)$, the space a^\perp is a hyperplane of V . Let $l = [a, b]$ be a projective line of $\text{PG}(V)$ through $[a]$ not contained in $[a^\perp]$. Then $f(a, b) \neq 0$. Moreover,

$$q(a\lambda + b) = q(a) \circ \lambda + q(b) + \overline{\lambda^\sigma f(a, b)} = q(b) + \overline{\lambda^\sigma f(a, b)} \quad (16)$$

by (Q2) and since $q(a) = \overline{0}$. As $f(a, b) \neq 0$, there exists a scalar $\lambda \in K$ such that $q(b) + \overline{\lambda^\sigma f(a, b)} = \overline{0}$. Then $q(a\lambda + b) = \overline{0}$ by (16). So, the vector $b_l := a\lambda + b$ is q -singular and $[b_l] \neq [a]$.

Let Λ_a be the set of lines of $\text{PG}(V)$ that contain $[a]$ but are not contained in $[a^\perp]$. By the previous paragraph, every line $l \in \Lambda_a$ contains a q -singular point $[b_l] \neq [a]$. Let $\Pi_a := \{[b_l]\}_{l \in \Lambda_a}$. Then Π_a is contained in P_q and spans $\text{PG}(V)$. Hence $\langle P_q \rangle = \text{PG}(V)$. \square

If P_q spans $\text{PG}(V)$ then the inclusion mapping $e_q : S_q \rightarrow \text{PG}(V)$ is a projective embedding in the sense of Subsection 1.3.3.

We know that S_q is a subspace of S_f (Proposition 2.9), but it could be a proper subspace of S_f , namely vectors $x \in V$ might exist such that $f(x, x) = 0$ but $q(x) \neq \overline{0}$. Nevertheless, the following holds.

Lemma 2.13 *For $x \in V$, if $f(x, x) = 0$ then $q(x) \in \overline{K}^\circ$.*

Proof. Recall that $\overline{K}^\circ = K^{\sigma, \varepsilon} / K_{\sigma, \varepsilon}$ (Lemma 2.2). Let $f(x, x) = 0$. Then

$$\begin{aligned} q(x) \circ (\lambda + \mu) &= q(x(\lambda + \mu)) = q(x\lambda) + q(x\mu) + \overline{\lambda^\sigma f(x, x)} \mu = \\ &= q(x\lambda) + q(x\mu) = q(x) \circ \lambda + q(x) \circ \mu \end{aligned}$$

for any choice of $\lambda, \mu \in K$. Let $t \in K$ be such that $q(x) = \bar{t}$. By the above, we have $(\lambda + \mu)^\sigma t(\lambda + \mu) \equiv \lambda^\sigma t\lambda + \mu^\sigma t\mu \pmod{K_{\sigma, \varepsilon}}$. Hence

$$\lambda^\sigma t\mu + \mu^\sigma t\lambda \in K_{\sigma, \varepsilon}. \quad (17)$$

Recalling that $\lambda^\sigma t\mu - (\lambda^\sigma t\mu)^\sigma \varepsilon \in K_{\sigma, \varepsilon}$ and $(\lambda^\sigma t\mu)^\sigma \varepsilon = \mu^\sigma t^\sigma \varepsilon \lambda$, from (17) we obtain that $\mu^\sigma t\lambda + \mu^\sigma t^\sigma \varepsilon \lambda \in K_{\sigma, \varepsilon}$, namely

$$\mu^\sigma (t + t^\sigma \varepsilon) \lambda \in K_{\sigma, \varepsilon}. \quad (18)$$

As $K_{\sigma, \varepsilon} \neq K$ by assumption and (18) holds for any choice of $\lambda, \mu \in K$, we obtain that $t + t^\sigma \varepsilon = 0$, namely $t \in K^{\sigma, \varepsilon}$. Hence $\bar{t} \in K^{\sigma, \varepsilon} / K_{\sigma, \varepsilon} = \overline{K}^\circ$. \square

Proposition 2.14 *Let (σ, ε) be of trace type. Then $S_q = S_f$.*

Proof. Let (σ, ε) be of trace type. Then $\overline{K}^\circ = \bar{0}$, by claim (1) of Corollary 2.3. Lemma 2.13 now implies that all f -isotropic vectors are q -singular, namely $P_f \subseteq P_q$. Therefore $S_q = S_f$, since S_q is a subspace of S_f . \square

2.3.3 Proportionality of pseudo-quadratic forms

In this subsection we adopt the notation of Subsection 2.1.4, thus denoting the group $\overline{K} = K / K_{\sigma, \varepsilon}$ by the symbol $\overline{K}^{\sigma, \varepsilon}$.

Assuming that $K_{\sigma, \varepsilon} \neq K$, let $q : V \rightarrow \overline{K}^{\sigma, \varepsilon}$ be a non-trivial (σ, ε) -quadratic form and let f be its sesquilinearization. Given a scalar $\kappa \in K - \{0\}$, let $(\sigma', \varepsilon') := \kappa \cdot (\sigma, \varepsilon)$. Let $\kappa q : V \rightarrow \overline{K}^{\sigma', \varepsilon'}$ map every $x \in V$ onto $\kappa q(x) \in \overline{K}^{\sigma', \varepsilon'}$ (well defined by Lemma 2.4). Then κq is a (σ', ε') -quadratic form and κf is the sesquilinearization of κq (Tits [7, Chapter 8]). Clearly, $S_{q'} = S_q$. We say that q and q' are *proportional*.

Proposition 2.15 *For $i = 1, 2$, let $q_i : V \rightarrow \overline{K}^{\sigma_i, \varepsilon_i}$ be a non-trivial $(\sigma_i, \varepsilon_i)$ -quadratic form such that S_{q_i} has non-degenerate rank at least 2. Suppose that $S_{q_1} = S_{q_2}$. Then q_1 and q_2 are proportional.*

Proof. This proposition is well known (see e.g. Tits [7, Chapter 8]). Nevertheless we give a sketch of the proof here, since in the Section 3 we will need it for reference.

Let f_1 and f_2 be the sesquilinearizations of q_1 and q_2 . By Proposition 2.12, for $i = 1, 2$ the set P_{q_i} spans $\text{PG}(V)$. Moreover S_{q_i} is a subspace of S_{f_i} . By assumption, the polar space S_{q_i} has non-degenerate rank at least 2. Hence the equality $S_{q_1} = S_{q_2}$ forces f_1 and f_2 to be proportional, by Proposition 2.6. It follows that q_1 and q_2 admit proportional facilitating forms (see definition (14), with a basis of singular vectors). Hence they are proportional. \square

3 Generalized pseudo-quadratic forms

In this section we propose a generalization of pseudo-quadratic forms and we show that all what we have said on the latters in the previous section remains valid in this more general context.

3.1 Definition and basic properties

Given a division ring K and an admissible pair (σ, ε) of K , let \overline{R} be a \circ -closed subgroup of \overline{K} (see Subsection 2.1.2). We denote by R the pre-image of \overline{R} by the projection $t \mapsto \bar{t} = t + K_{\sigma, \varepsilon}$ of K onto $\overline{K} = K/K_{\sigma, \varepsilon}$:

$$R := \{t \mid \bar{t} \in \overline{R}\}. \quad (19)$$

We recall that a scalar multiplication is induced by \circ on the factor group $\overline{K}/\overline{R}$, as explained in (8). Clearly \overline{R} is the null element of $\overline{K}/\overline{R}$. When \overline{R} is given this role, we denote it by the symbol $0_{\overline{R}}$.

Given a K -vector space V , a *generalized (σ, ε) -quadratic form* (also *generalized pseudo-quadratic form*) is a map $q : V \rightarrow \overline{K}/\overline{R}$ such that

- (Q'1) $q(x\lambda) = q(x) \circ \lambda$ for any $\lambda \in K$;
- (Q'2) there exists a trace-valued (σ, ε) -sesquilinear form $f : V \times V \rightarrow K$ such that $q(x + y) = q(x) + q(y) + (f(x, y) + \overline{R})$ for any choice of $x, y \in V$.

We call \overline{R} the *co-defect* of q . With this terminology, a pseudo-quadratic form is just a generalized pseudo-quadratic form with trivial co-defect.

Remark. A motivation for the choice of the word *co-defect* will be given in Subsection 4.2.3, where we will show that the co-defect \overline{R} of q is involved in the defect of a suitable pseudo-quadratic form, called the dominant cover of q .

A sesquilinear form f as in (Q'2) is called a *sesquilinearization* of q .

Lemma 3.1 *Let $q : V \rightarrow \overline{K}/\overline{R}$ be a generalized pseudo-quadratic form.*

- (1) *If $\overline{R} \neq \overline{K}$ then q admits exactly one sesquilinearization.*
- (2) *Let $\overline{R} = \overline{K}$. Then every trace-valued (σ, ε) -sesquilinear form on V is a sesquilinearization of q .*

Proof. Claim (2) is obvious. Claim (1) can be proved by the same argument used to prove Lemma 2.8, but for replacing $K_{\sigma, \varepsilon}$ with the group R defined in (19). \square

Every generalized (σ, ε) -quadratic form also admits a *facilitating form*, namely a σ -sesquilinear form $g : V \times V \rightarrow K$ such that

$$q(x) = \overline{g(x, x)} + \overline{R} \text{ for any } x \in V. \quad (20)$$

If $\overline{R} = \overline{K}$ then every σ -sesquilinear form is a facilitating form for q . Let $\overline{R} \neq \overline{K}$ and let f be the sesquilinearization of q . It is straightforward to prove that all facilitating forms of q are obtained as follows. Let $(e_i)_{i \in I}$ be a basis of V and $<$ a total ordering of I . For every $i \in I$ let $g_i \in K$ be such that $q(e_i) = \bar{g}_i + \overline{R}$. For $x, y \in V$ let $g(x, y)$ be defined as in (14). Then g is a facilitating form for q . Moreover $f(x, y) = g(x, y) + g(y, x)^\sigma \varepsilon$, as in (15).

Conversely, given a σ -sesquilinear form $g : V \times V \rightarrow K$ and an element $\varepsilon \in K$ forming an admissible pair with σ , let $q : V \rightarrow \overline{K}$ be defined as in (20). Then q is a generalized (σ, ε) -quadratic form and the form f defined as in (15) is the sesquilinearization of q .

Theorem 3.2 *Let $\overline{R} \neq \overline{K}$. Let $q : V \rightarrow \overline{K}/\overline{R}$ be a generalized (σ, ε) -quadratic form, let f be its sesquilinearization and R as in (19). Then all the following hold:*

- (1) *We have $\overline{R} \subseteq \overline{K}^\circ$. In other words, \overline{R} is a vector subspace of \overline{K}° .*
- (2) *For every vector $x \in V$, if $q(x) = 0_{\overline{R}}$ then $f(x, x) = 0$.*
- (3) *Let $x \in V$ be such that $f(x, x) = 0$. Then $q(x) \in \overline{K}^\circ/\overline{R}$ (well defined in view of claim (1)).*

Proof. In view of (Q'1) and (Q'2), we have

$$q(x) \circ (\lambda + \mu) + \overline{R} = q(x(\lambda + \mu)) = q(x) \circ \lambda + q(x) \circ \mu + \lambda^\sigma f(x, x) \mu$$

for any choice of $\lambda, \mu \in K$. Therefore, given $t \in K$ such that $\bar{t} + \overline{R} = q(x)$, we have $\lambda^\sigma t \mu + \mu^\sigma t \lambda - \lambda^\sigma f(x, x) \mu \in R$. As $K_{\sigma, \varepsilon} \subseteq R$ and $\mu^\sigma t \lambda - \lambda^\sigma t^\sigma \varepsilon \mu = \mu^\sigma t \lambda - (\mu^\sigma t \lambda)^\sigma \varepsilon \in K_{\sigma, \varepsilon}$ we obtain that $\lambda^\sigma t \mu + \lambda^\sigma t^\sigma \varepsilon \mu - \lambda^\sigma f(x, x) \mu \in R$, namely

$$\lambda^\sigma (t + t^\sigma \varepsilon - f(x, x)) \mu \in R \text{ for any choice of } \lambda, \mu \in K. \quad (21)$$

As $R \subset K$ by assumption, (21) forces

$$t + t^\sigma \varepsilon = f(x, x). \quad (22)$$

However we can replace t with $t + r$ in (22), for any $r \in R$. By comparing the new equation thus obtained with (22) we obtain that $r + r^\sigma \varepsilon = 0$ for any $r \in R$, namely $R \subseteq K^{\sigma, \varepsilon}$. Equivalently, $\overline{R} \subseteq K^{\sigma, \varepsilon}/K_{\sigma, \varepsilon} = \overline{K}^\circ$, as claimed in (1). As \overline{R} is \circ -closed by assumption, \overline{R} is a vector subspace of the K -vector space \overline{K}° .

Claims (2) and (3) can be proved in the same way as claim (1) of Proposition 2.9 and Lemma 2.13, but for replacing $K_{\sigma, \varepsilon}$ with R in those proofs. \square

Note that $f(x, x) \in K_{\sigma, -\varepsilon}$ for any $x \in V$ because f is trace-valued. If $\text{char}(K) = 2$ then $\varepsilon = -\varepsilon$. In this case $f(x, x) \in K_{\sigma, \varepsilon} \subseteq R$ for any $x \in V$.

Corollary 3.3 *Let (σ, ε) be of trace type and $\overline{R} \neq \overline{K}$. Then $\overline{R} = \{0\}$, whence q is pseudo-quadratic.*

Proof. By claim (1) of Corollary 2.3, the pairs (σ, ε) is of trace type if and only if $\overline{K}^\circ = \{\bar{0}\}$. Moreover, by claim (1) of Theorem 3.2, either $\overline{R} = \overline{K}$ or $\overline{R} \subseteq \overline{K}^\circ$. Therefore, if $\overline{R} \subset \overline{K}$ and $\overline{K}^\circ = \{\bar{0}\}$ then $\overline{R} = \{\bar{0}\}$. \square

A generalized pseudo-quadratic form $q : V \rightarrow \overline{K}/\overline{R}$ is said to be *trivial* if $q(x) = 0_{\overline{R}}$ for every $x \in V$.

Proposition 3.4 *The form q is trivial if and only if one of the following holds:*

- (1) $\overline{R} = \overline{K}$.
- (2) *We have $\overline{R} \neq \overline{K}$ but the sesquilinearization of q is trivial and there exists a basis $(e_i)_{i \in I}$ of V such that $q(e_i) = 0_{\overline{R}}$ for every $i \in I$.*

Proof. Clearly, if $\overline{R} = \overline{K}$ then q is trivial. Assume that $\overline{R} \subset \overline{K}$. Then q admits a unique sesquilinearization f , by Lemma 3.1. Suppose that nevertheless q is trivial. Then $f(x, y) \in R$ for any $x, y \in V$. Accordingly,

$$\lambda^\sigma f(x, y) \mu \in R \text{ for any choice of } \lambda, \mu \in K \text{ and } x, y \in V. \quad (23)$$

If $f(x, y) \neq 0$ for a pair (x, y) , then (23) forces $R = K$, contrary to the assumptions made on \overline{R} . It follows that $f(x, y)$ is the trivial form.

Conversely, let f be trivial and $q(e_i) = 0_{\overline{R}}$ for every $i \in I$. Then the form g defined as in (15) but with $g_i = 0$ for every $i \in I$, is trivial. However g is a facilitating form of q . Hence q is trivial as well. \square

3.2 The polar space S_q

For the rest of this section we assume that q is non-trivial. In particular, $\overline{R} \neq \overline{K}$. As above, f stands for the sesquilinearization of q . The symbol R is given the meaning stated in (19).

As in the case of pseudo-quadratic forms, we say that a vector $x \in V$ is *singular* for q (also *q -singular*) if $q(x) = 0_{\overline{R}}$. A subspace X of V is said to be *totally singular* for q (also *totally q -singular*) if $q(x) = 0_{\overline{R}}$ for every $x \in X$.

Clearly, if $q(x) = 0_{\overline{R}}$ for a vector $x \in V$ then $q(x\lambda) = 0_{\overline{R}}$ for any $\lambda \in K$. We say that a point $[x]$ of PG is *q -singular* (also *q -singular*) if x is q -singular. A subspace of $\text{PG}(V)$ is said to be *totally singular* for q (*totally q -singular*) if all of its points are q -singular.

Let P_q be the set of q -singular points of $\text{PG}(V)$. By claim (2) of Theorem 3.2, if a point of $\text{PG}(V)$ is q -singular then it is f -isotropic. In short, $P_q \subseteq P_f$.

Proposition 3.5 *A line $[x, y]$ of $\text{PG}(V)$ is totally q -singular if and only if $q(x) = q(y) = 0_{\overline{R}}$ and $f(x, y) = 0$.*

Proof. This statement can be proved in the same way as claim (2) of Proposition 2.9, but for replacing $K_{\sigma, \varepsilon}$ with R in that proof. \square

Corollary 3.6 *A subspace $[x_1, x_2, \dots, x_k]$ of $\text{PG}(V)$ is totally q -singular if and only if it is totally isotropic for f and $q(x_1) = q(x_2) = \dots = q(x_k) = 0_{\overline{R}}$.*

Proof. This immediately follows from Proposition 3.5. \square

Corollary 3.7 *Let (σ, ε) be of trace type. Then a subspace of $\text{PG}(V)$ is totally q -singular if and only if it is totally f -isotropic.*

Proof. By Corollary 3.3, when (σ, ε) is of trace type the form q is pseudo-quadratic. The conclusion follows from Proposition 2.14. \square

Assuming that $P_q \neq \emptyset$, let L_q be the set of totally q -singular lines of $\text{PG}(V)$ and put $S_q = (P_q, L_q)$. In view of Proposition 3.6, the point-line geometry S_q is a subspace of the polar space $S_f = (P_f, L_f)$ associated to f . It readily follows that S_q is itself a polar space. Its radical is a (possibly empty) subspace of $[\text{Rad}(f)]$, equal to $P_q \cap [\text{Rad}(f)]$. Moreover, if (σ, ε) is of trace type then $S_q = S_f$, by Corollary 3.7.

We call S_q the polar space *associated to q* . The q -singular vectors of $\text{Rad}(f)$ form a subspace of $\text{Rad}(f)$, henceforth called the *radical* of q and denoted by the symbol $\text{Rad}(q)$. We say that q is *singular* (also *degenerate*) if $\text{Rad}(q) \neq \{0\}$, namely S_q is degenerate. We call $\text{Rad}(f)$ the *defect* of q , let q be singular or not.

Let $q|_{\text{Rad}(f)}$ be the mapping induced by q on $\text{Rad}(f)$. Clearly $q|_{\text{Rad}(f)}$ is additive. By this fact and claim (3) of Theorem 3.2 we get the following:

Proposition 3.8 *The mapping $q|_{\text{Rad}(f)}$ is a homomorphism of K -vector spaces from $\text{Rad}(f)$ to $\overline{K}^\circ/\overline{R}$ and $\text{Rad}(q)$ is the kernel of this homomorphism.*

Consequently, the quotient space $\text{Rad}(f)/\text{Rad}(q)$ is isomorphic to the image $\text{Im}(q|_{\text{Rad}(f)})$ of $q|_{\text{Rad}(f)}$ and the latter is a vector subspace of $\overline{K}^\circ/\overline{R}$.

Remark. A result similar to Proposition 3.8 holds with $\text{Rad}(f)$ replaced by any totally f -isotropic subspace X of V and $\text{Rad}(q)$ replaced by the set of q -singular vectors of X .

Proposition 3.9 *Either P_q is totally q -singular or it spans $\text{PG}(V)$.*

Proof. The proof given for Proposition 2.12 works for this statement as well, but for replacing $K_{\sigma, \varepsilon}$ with R in that proof. \square

When P_q spans $\text{PG}(V)$ the inclusion mapping $e_q : S_q \rightarrow \text{PG}(V)$ is an embedding as defined in Subsection 1.3.3.

3.3 A facilitating form

We keep the hypotheses and the notation of the previous subsection. In particular, $\overline{R} \neq \overline{K}$, f is the sesquilinearization of q and P_q is the set of q -singular points of $\text{PG}(V)$. We also assume that P_q spans $\text{PG}(V)$. Hence V admits a basis formed by q -singular vectors. We call such a basis a *q -singular basis*.

Let $E = (e_i)_{i \in I}$ be a q -singular basis of V . Given a total ordering $<$ on the set I of indices, let $g_E : V \times V \rightarrow K$ be the σ -seilinear form defined as follows:

$$g_E\left(\sum_i e_i \lambda_i, \sum_j e_j \mu_j\right) := \sum_{i < j} \lambda_i^\sigma f(e_i, e_j) \mu_j. \quad (24)$$

Since $q(e_i) = 0_{\bar{R}}$ for every $i \in I$, the form g_E is a facilitating form for q , namely

$$q(x) = \overline{g_E(x, x)} + \bar{R} = \sum_{i < j} \overline{\lambda_i^\sigma f(e_i, e_j) \lambda_j} + \bar{R}$$

for every vector $x = \sum_{i \in I} e_i \lambda_i$ of V . Clearly, the coset $\overline{g_E(x, x)} + \bar{R}$ does not depend on the choice of the q -singular basis E but the scalar $g_E(x, x)$ obviously depends on that choice. The value $g_E(x, x)$ also depends on it, to some extent. In order to make this remark less vague, we need a few additional definitions.

Let $E = (e_i)_{i \in I}$ and $E' = (e'_i)_{i \in I}$ be two ordered q -singular bases of V . Let $\bar{R}_{E, E'}$ be the \circ -closed subgroup of \bar{K} spanned by the family $\{\overline{g_{E'}(e_i, e_i)}\}_{i \in I}$ and let $\delta_{E, E'} : V \in \bar{K}$ be the mapping defined as follows:

$$\delta_{E, E'}(x) := \overline{g_E(x, x)} - \overline{g_{E'}(x, x)}.$$

Clearly, $\delta_{E, E'}(x) + \bar{R} = q(x) - q(x) = 0_{\bar{R}}$. Therefore $\delta_{E, E'}(V) \subseteq \bar{R}$. Recall that \bar{R} is a vector subspace of \bar{K}° , as we know from Theorem 3.2, (1).

Lemma 3.10 *The group $\bar{R}_{E, E'}$, equipped with the scalar multiplication \circ , is a vector subspace of \bar{R} and $\delta_{E, E'}$ is a surjective linear map from V to $\bar{R}_{E, E'}$. Moreover $\delta_{E', E} = -\delta_{E, E'}$ and $\bar{R}_{E, E'} = \bar{R}_{E', E}$.*

Proof. For $x \in V$ let $x = \sum_i e_i \lambda_i = \sum_i e'_i \lambda'_i$. Then

$$\left. \begin{aligned} g_E(x, x) &= \sum_{i < j} \lambda_i^\sigma f(e_i, e_j) \lambda_j, \\ g_{E'}(x, x) &= \sum_{i < j} (\lambda'_i)^\sigma f(e'_i, e'_j) \lambda'_j. \end{aligned} \right\} \quad (25)$$

Moreover, there exists scalars α_{ij} ($i, j \in I$) such that

$$e_k = \sum_i e'_i \alpha_{ik} \text{ for all } k \in I. \quad (26)$$

Hence

$$\lambda'_k = \sum_i \alpha_{ki} \lambda_i \text{ for all } k \in I. \quad (27)$$

Substituting (26) in the first equality of (25) and (27) in the second one we get

$$\left. \begin{aligned} g_E(x, x) &= \sum_{i < j} \sum_{k, h} \lambda_i^\sigma \alpha_{k, i}^\sigma f(e'_k, e'_h) \alpha_{h, j} \lambda_j, \\ g_{E'}(x, x) &= \sum_{i < j} \sum_{k, h} \lambda_k^\sigma \alpha_{i, k}^\sigma f(e'_i, e'_h) \alpha_{j, h} \lambda_h. \end{aligned} \right\} \quad (28)$$

By changing indices in the second equation of (28), we can rewrite the two equations of (28) as follows:

$$\left. \begin{aligned} g_E(x, x) &= \sum_{i, j, k, h; i < j} \lambda_i^\sigma \alpha_{k, i}^\sigma f(e'_k, e'_h) \alpha_{h, j} \lambda_j, \\ g_{E'}(x, x) &= \sum_{i, j, k, h; k < h} \lambda_i^\sigma \alpha_{k, i}^\sigma f(e'_k, e'_h) \alpha_{h, j} \lambda_j. \end{aligned} \right\} \quad (29)$$

Recalling that $f(e'_h, e'_k) = f(e'_k, e'_h)^\sigma \varepsilon$, that

$$\begin{aligned} & \lambda_i^\sigma \alpha_{k,i}^\sigma f(e'_k, e'_h) \alpha_{h,j} \lambda_j - \lambda_j^\sigma \alpha_{h,j}^\sigma f(e'_k, e'_h)^\sigma \varepsilon \alpha_{k,i} \lambda_i = \\ & = (\lambda_i^\sigma \alpha_{k,i}^\sigma f(e'_k, e'_h) \alpha_{h,j} \lambda_j) - (\lambda_j^\sigma \alpha_{h,j}^\sigma f(e'_k, e'_h)^\sigma \varepsilon \alpha_{k,i} \lambda_i) \in K_{\sigma, \varepsilon}, \end{aligned}$$

and $f(e'_k, e'_k) = 0$ (by (2) of Theorem 3.2 and since $q(e'_k) = 0_{\overline{R}}$ by assumption), we can rewrite the two equalities of (29) as follows:

$$\begin{aligned} g_E(x, x) &= \sum_{i < j, k < h} \lambda_i^\sigma \alpha_{k,i}^\sigma (f(e'_k, e'_h) + f(e'_k, e'_h)^\sigma \varepsilon) \alpha_{h,j} \lambda_j, \\ g_{E'}(x, x) + K_{\sigma, \varepsilon} &= \sum_{i < j, k < h} \lambda_i^\sigma \alpha_{k,i}^\sigma (f(e'_k, e'_h) + f(e'_k, e'_h)^\sigma \varepsilon) \alpha_{h,j} \lambda_j + \\ &+ \sum_{k, h, i; k < h} \lambda_i^\sigma \alpha_{k,i}^\sigma f(e'_k, e'_h) \alpha_{h,i} \lambda_i. \end{aligned}$$

Consequently,

$$\overline{g_E(x, x)} - \overline{g_{E'}(x, x)} = - \sum_{k, h, i; k < h} \overline{\alpha_{k,i}^\sigma f(e'_k, e'_h) \alpha_{h,i}} \circ \lambda_i. \quad (30)$$

However $\sum_{k < h} \alpha_{k,i}^\sigma f(e'_k, e'_h) \alpha_{h,i} = g_{E'}(\sum_k e'_k \alpha_{k,i}, \sum_k e'_k \alpha_{k,i}) = g_{E'}(e_i, e_i)$ by definition of $g_{E'}$ and (26). Substituting in (30) we obtain:

$$\overline{g_E(x, x)} - \overline{g_{E'}(x, x)} = - \sum_i \overline{g_{E'}(e_i, e_i)} \circ \lambda_i. \quad (31)$$

According to (31), we have $\overline{R}_{E, E'} = \delta_{E, E'}(V) (\subseteq \overline{R}$, as previously remarked). Therefore $\overline{R}_{E, E'}$ is a vector subspace of \overline{R} . Equation (31) also shows that $\delta_{E, E'}$ is a linear mapping from V to $\overline{R}_{E, E'}$. Clearly, $\delta_{E', E} = -\delta_{E, E'}$. Whence $\overline{R}_{E, E'} = \overline{R}_{E', E}$. \square

We call $\delta_{E, E'}$ and $\overline{R}_{E, E'}$ the *difference-map* and the *difference-space* relative to the pair (E, E') of q -singular bases.

Remark. Only q -singular bases are considered in Lemma 3.10, but the statement of Lemma 3.10 holds for any pair of bases formed by f -isotropic vectors, except that in this more general setting no closed subgroup \overline{R} is given in advance. Instead of \overline{R} we must consider the closed subgroups \overline{R}_E and $\overline{R}_{E'}$ of \overline{K} generated by the sets $\{\overline{g_E(x, x)}\}_{[x] \in P_f}$ and $\{\overline{g_{E'}(x, x)}\}_{[x] \in P_f}$ respectively. The proof of Lemma 3.10 shows that $\delta_{E, E'}(V) = \overline{R}_{E, E'} \subseteq \overline{R}_{E'}$, whence $\overline{R}_E \subseteq \overline{R}_{E'}$. By symmetry, $\overline{R}_E \supseteq \overline{R}_{E'}$. Finally $\overline{R}_E = \overline{R}_{E'}$.

For every $x \in V$, put $\gamma_E(x) := \overline{g_E(x, x)}$ and $\gamma_{E'}(x) := \overline{g_{E'}(x, x)}$. Then both γ_E and $\gamma_{E'}$ are pseudo-quadratic forms. By Lemma 2.13, the group $\overline{R}_E = \overline{R}_{E'}$ is a vector subspace of \overline{K}° .

3.4 Isomorphism and weak isomorphism

Given two generalized (σ, ε) -quadratic forms $q : V \rightarrow \overline{K}/\overline{R}$ and $q' : V' \rightarrow \overline{K}/\overline{R}$ with the same co-defect \overline{R} , we say that q and q' are *isomorphic* if there exists a bijective linear mapping $\alpha : V \rightarrow V'$ such that $q'(\alpha(x)) = q(x)$ for every $x \in V$.

A broader notion of isomorphism can also be stated, where α is allowed to be semi-linear. In view of that we need a few preliminaries on automorphisms of K .

We say that an automorphism ρ of K *stabilizes* a given admissible pair (σ, ε) if $\rho\sigma = \sigma\rho$ and $\varepsilon^\rho = \varepsilon$.

Let $\rho \in \text{Aut}(K)$ stabilize (σ, ε) . Then ρ stabilizes both $K_{\sigma, \varepsilon}$ and $K^{\sigma, \varepsilon}$. Thus ρ induces on the group $\overline{K} = K/K_{\sigma, \varepsilon}$ an automorphism $\bar{\rho}$ stabilizing $\overline{K}^\circ = K^{\sigma, \varepsilon}/K_{\sigma, \varepsilon}$. Moreover, $(\bar{t} \circ \lambda)^{\bar{\rho}} = \bar{t}^{\bar{\rho}} \circ \lambda^\rho$ for every element $\bar{t} \in \overline{K}$ and every scalar $\lambda \in K$. Hence the automorphism of \overline{K}° induced by $\bar{\rho}$ is a bijective ρ -semi-linear mapping of the K -vector space \overline{K}° .

Given a \circ -closed subgroup \overline{R} of \overline{K} , let $\overline{R}^{\bar{\rho}}$ be the image of \overline{R} by $\bar{\rho}$. Then $\overline{R}^{\bar{\rho}}$ is \circ -closed and $\bar{\rho}$ induces an isomorphism from $\overline{K}/\overline{R}$ to $\overline{K}/\overline{R}^{\bar{\rho}}$. Clearly, for every element $\bar{t} + \overline{R}$ of $\overline{K}/\overline{R}$ and every $\lambda \in K$ we have

$$((\bar{t} + \overline{R}) \circ \lambda)^{\bar{\rho}} = (\bar{t}^{\bar{\rho}} + \overline{R}^{\bar{\rho}}) \circ \lambda^\rho = (\bar{t} + \overline{R})^{\bar{\rho}} \circ \lambda^\rho.$$

We can now loose our previous definition of isomorphism.

Let \overline{R} and \overline{R}' be two \circ -closed subgroups of \overline{K} . We say that two generalized (σ, ε) -quadratic forms $q : V \rightarrow \overline{K}/\overline{R}$ and $q' : V' \rightarrow \overline{K}/\overline{R}'$ are *weakly isomorphic* if there exists an automorphism ρ of K stabilizing (σ, ε) and such that $\overline{R}^{\bar{\rho}} = \overline{R}'$ and a ρ -semi-linear mapping $\alpha : V \rightarrow V'$ such that $q'(\alpha(x)) = q(x)^{\bar{\rho}}$ for every $x \in V$.

3.5 Proportionality

For $i = 1, 2$ let $(\sigma_i, \varepsilon_i)$ be an admissible pair of K and \overline{R}_i a \circ_{σ_i} -closed subgroup of $\overline{K}^{\sigma_i, \varepsilon_i} = K/K_{\sigma_i, \varepsilon_i}$ (notation as in Subsection 2.1.4). Let $q_i : V \rightarrow \overline{K}^{\sigma_i, \varepsilon_i}/\overline{R}_i$ be a non-trivial generalized $(\sigma_i, \varepsilon_i)$ -quadratic form and let f_i be its sesquilinearization. We say that q_1 and q_2 are *proportional* if there exists a scalar $\kappa \in K - \{0\}$ such that $(\sigma_2, \varepsilon_2) = \kappa \cdot (\sigma_1, \varepsilon_1)$, $\overline{R}_2 = \kappa \overline{R}_1$ and $q_2(x) = \kappa q_1(x)$ for every $x \in V$. If this is the case then we write $q_2 = \kappa q_1$. Clearly, if $q_2 = \kappa q_1$ then $f_2 = \kappa f_1$ and $S_{q_1} = S_{q_2}$.

Theorem 3.11 *Let $q_1 : V \rightarrow \overline{K}^{\sigma_1, \varepsilon_1}/\overline{R}_1$ and $q_2 : V \rightarrow \overline{K}^{\sigma_2, \varepsilon_2}/\overline{R}_2$ be generalized pseudo-quadratic forms such that $S_{q_1} = S_{q_2}$. Assume that the polar space $S := S_{q_1} = S_{q_2}$ has non-degenerate rank at least 2. Then q_1 and q_2 are proportional.*

Proof. By the same argument used in the proof of Proposition 2.15 we obtain that f_1 and f_2 are proportional. Thus, modulo replacing q_1 with κq_1 for a suitable $\kappa \in K - \{0\}$ we may assume that $f_1 = f_2 = f$, say. Hence $(\sigma_1, \varepsilon_1) = (\sigma_2, \varepsilon_2)$ and $\overline{K}^{\sigma_1, \varepsilon_1} = \overline{K}^{\sigma_2, \varepsilon_2} =: \overline{K}$. We must prove that we also have $q_1 = q_2$. As $f_1 = f_2 = f$, we can choose the same facilitating form g for q_1 and q_2 , defining it as in (24) of Subsection 3.3. So, for every $x \in V$, we can choose the same representative $\bar{t}_x \in \overline{K}$ for both $q_1(x)$ and $q_2(x)$. In order to prove that $q_1 = q_2$ we must only show that $\overline{R}_1 = \overline{R}_2$.

Let $\bar{r} \in \bar{R}_1$. Let a and b be two vectors such that $f(a, b) = 1$ and $[a], [b] \in S$ ($:= S_{q_1} = S_{q_2}$). Such a pair of vectors exists in view of the hypotheses made on S . Let $r \in K$ be such that $\bar{r} \in \bar{R}_1$. Then $q_1(a + br) = \bar{r} + \bar{R}_1 = \bar{R}_1$. Hence $[a + br] \in S$. On the other hand, $q_2(a + br) = \bar{r} + \bar{R}_2$. As $[a + br] \in S$, the vector $a + br$ is also q_2 -singular, namely $\bar{r} \in \bar{R}_2$. It follows that $\bar{R}_1 \subseteq \bar{R}_2$. By symmetry, $\bar{R}_2 \subseteq \bar{R}_1$. Hence $\bar{R}_1 = \bar{R}_2$. \square

4 Quotients and covers

In this section $q : V \rightarrow \bar{K}/\bar{R}$ is a given non-trivial generalized (σ, ε) -quadratic form, $f : V \times V \rightarrow K$ is its sesquilinearization and $S_q = (P_q, L_q)$ is the polar space associated to q . As q is non-trivial, the form f is non-trivial as well, by Proposition 3.4. Moreover, \bar{R} is a vector subspace of \bar{K}° , by Theorem 3.2, (1).

We assume that P_q is not totally singular. Hence it spans $\text{PG}(V)$ (Proposition 3.9). Therefore the inclusion mapping $e_q : S_q \rightarrow \text{PG}(V)$ is an embedding of S_q in $\text{PG}(V)$.

Recall that $[\text{Rad}(q)] = [\text{Rad}(f)] \cap P_q$ is the radical of S_q .

4.1 Quotients

According to the definitions stated in Subsection 1.3.3, a subspace U of V defines a quotient of the embedding $e_q : S_q \rightarrow \text{PG}(V)$ precisely when $[U] \cap P_q = \emptyset$ and $[U] \cap [a, b] = \emptyset$ for any two distinct points $[a], [b] \in P_q$.

Proposition 4.1 *A subspace U of V defines a quotient of the embedding e_q if and only if $U \subseteq \text{Rad}(f)$ and $U \cap \text{Rad}(q) = 0$.*

Proof. This proposition is a special case of the following more general statement on quotients of embeddings of point-line geometries.

Let $e : G \rightarrow \text{PG}(V)$ be a projective embedding of a point-line geometry $G = (P, L)$. Let W be a subspace of V such that a point $[v]$ of $\text{PG}(V) - e(P)$ belongs to $[W]$ if and only if every line of $\text{PG}(V)$ through $[v]$ meets $e(P)$ in at most one point. Then a subspace U of V defines a quotient of the embedding e if and only if $[U] \cap e(P) = \emptyset$ and $U \subseteq W$.

The proof of this claim is easy. We leave it to the reader. In view of the above, in order to prove Proposition 4.1 we only must prove that a point $[v]$ of $\text{PG}(V) - P_q$ belongs to $[\text{Rad}(f)]$ if and only if every projective line through $[v]$ meets P_q in at most one point.

Given a point $[v] \notin P_q$, assume firstly that every projective line through $[v]$ meets P_q in at most one point. Let $[a] \in P_q$. Then $q(a) = 0_{\bar{R}}$. Consequently, $q(a\lambda + v) = q(v) + (\lambda^\sigma \overline{f(a, v)} + \bar{R})$ for any $\lambda \in K$. It follows that if $f(a, v) \neq 0$ then a scalar $\lambda \in K$ exists such that $q(a\lambda + v) = 0_{\bar{R}}$. If this is the case then $[a, v]$ meets P_q in at least two points, namely $[a]$ and $[a\lambda + v]$, a contradiction with the hypotheses made on $[v]$. Therefore $f(a, v) = 0$. As this holds for any $[a] \in P_q$, we obtain that $P_q \subseteq [v]^\perp$. However P_q spans $\text{PG}(V)$, by assumption. Hence $V = [v]^\perp$, namely $v \in \text{Rad}(f)$.

Conversely, let $v \in \text{Rad}(f)$. Let $[a] \in P_q$. Then $q(a) = 0_{\bar{R}}$ and $f(a, v) = 0$ while $q(v) \neq 0_{\bar{R}}$ as $[v] \notin P_q$ by assumption. Hence $q(a\lambda + v) = q(v) \neq 0_{\bar{R}}$ for any $\lambda \in K$. This shows that $[a, v] \cap P_q = \{[a]\}$. Therefore every projective line through $[v]$ meets P_q in at most one point. \square

The next corollary immediately follows from Proposition 4.1.

Corollary 4.2 *If $\text{Rad}(q) = \text{Rad}(f)$ then the embedding e_q does not admit any proper quotient.*

For the rest of this subsection we assume that $\text{Rad}(q) \neq \text{Rad}(f)$. Hence S_q is a proper subspace of S_f . Consequently, (σ, ε) is not of trace type. In particular, $\text{char}(K) = 2$.

Let U be a subspace of $\text{Rad}(f)$ with $U \cap \text{Rad}(q) = 0$. By Proposition 3.8, the restriction of q to U is an injective linear mapping from U to the K -vector space \bar{K}°/\bar{R} . Hence the image $q(U)$ of U by q is a vector subspace of \bar{K}°/\bar{R} . Therefore there exists a unique subspace \bar{R}_U of \bar{K}° containing \bar{R} and such that $\bar{R}_U/\bar{R} = q(U)$. Let $q_U : V/U \rightarrow \bar{K}/\bar{R}_U$ be the mapping defined as follows:

$$q_U(x + U) = \bar{t} + \bar{R}_U \text{ for an element } t \in K \text{ such that } \bar{t} + \bar{R} = q(x).$$

Lemma 4.3 *The mapping q_U is well defined.*

Proof. Clearly, the coset $\bar{t} + \bar{R}_U$ does not depend on the choice of the representative \bar{t} of $q(x)$. It remains to prove that it neither depends on the choice of the vector x in the coset $x + U$.

Given $u \in U$, let $x' = x + u$ and let \bar{t}' be a representative of $q(x')$. Then $q(x') = q(x + u) = q(x) + q(u) + f(x, u) = q(x) + q(u)$ because $u \in U \subseteq \text{Rad}(f)$. However $q(u) \in \bar{R}_U/\bar{R}$ by definition of \bar{R}_U . Therefore $\bar{t} - \bar{t}' \in \bar{R}_U$, namely $\bar{t} + \bar{R}_U = \bar{t}' + \bar{R}_U$. \square

The sesquilinearization f of q induces a trace-valued (σ, ε) -sesquilinear form f_U on V/U . Explicitly,

$$f_U(x + U, y + U) := f(x, y).$$

This definition is consistent. Indeed, since $U \subseteq \text{Rad}(f)$, we have $f(x + u, y + v) = f(x, y)$ for any choice of $u, v \in U$. It is clear that, since f is trace-valued and non-trivial, f_U is trace-valued and non-trivial as well.

The proof of the following lemma is straightforward. We leave it to the reader.

Lemma 4.4 *The mapping q_U is a generalized (σ, ε) -quadratic form. The form f_U induced by f on V/U is a sesquilinearization of q_U .*

As f_U is non-trivial, the form q_U is non-trivial if and only if $\bar{R}_U \neq \bar{K}$, by Proposition 3.4. If this is the case then f_U is the unique sesquilinearization of q_U , by Lemma 3.1. Finally, Lemma 4.4 and claim (1) of Theorem 3.2 imply the following:

Corollary 4.5 *Let q_U be non-trivial. Then $\overline{R}_U \subseteq \overline{K}^\circ$.*

We call q_U the *quotient* of q by U . According to the notation of Subsection 3.2, when q_U is non-trivial we denote by P_{q_U} and L_{q_U} the set of q_U -singular points and totally q_U -singular lines of $\text{PG}(V/U)$, respectively. So, $S_{q_U} = (P_{q_U}, L_{q_U})$ is the polar space associated to q_U in $\text{PG}(V/U)$.

Theorem 4.6 *Let $\pi_U : V \rightarrow V/U$ be the projection of V onto V/U .*

- (1) *Let q_U be non-trivial. Then π_U induces an isomorphism from S_q to S_{q_U} .*
- (2) *Let q_U be trivial. Then both forms f and f_U are alternating and π_U induces an isomorphism from S_q to the polar space S_{f_U} associated to f_U .*

Proof. As U defines a quotient of S_q , every coset $x + U$ of U in V contains at most one q -singular vector. Therefore π_U induces an injective mapping on P_q . We firstly prove the following:

- (*) For every non-zero vector $x \in V$ we have $q_U(x + U) = 0_{\overline{R}_U}$ if and only if $x + u$ is q -singular for some $u \in U$.

The coset $x + U$ contains a q -singular vector if and only if $q(x + u) \in \overline{R}$ for some vector $u \in U$, namely $q(x) + q(u) \in \overline{R}$. (Recall that $f(x, u) = 0$ since $U \subseteq \text{Rad}(f)$). If this is the case then $q(x) \in \overline{R}_U/\overline{R}$, namely $q_U(x + U) = 0_{\overline{R}_U}$. Conversely, let $q_U(x + U) = 0_{\overline{R}_U}$. Then there exists an element $\bar{t} \in \overline{R}_U$ such that $q(x) = \bar{t} + \overline{R}$. By definition of \overline{R}_U , we have $\bar{t} + \overline{R} = q(u)$ for some $u \in U$. Hence $q(x - u) = 0_{\overline{R}}$, namely $x - u$ is q -singular. Claim (*) is proved.

Let q_U be non-trivial. By (*), the projection π_U induces a bijection from P_q to P_{q_U} . Two q_U -singular points $[x + U]$ and $[y + U]$ of $\text{PG}(V/U)$ are collinear in S_{q_U} if and only if $f_U(x + U, y + U) = 0$. By the definition of f_U , this condition is equivalent to $f(x, y) = 0$, which in its turn characterizes the collinearity of $[x]$ and $[y]$. Claim (1) of the theorem is proved.

Let q_U be trivial. Then (*) shows that π_U induces a bijection from P_q to the set of points of $\text{PG}(V/U)$. In other words, every coset $x + U$ of U other than U contains exactly one q -singular vector. We may assume that in a symbol as $x + U$ the letter x stands for the unique q -singular vector of $x + U$. With this convention, $f_U(x + U, x + U) = f(x, x)$ (by definition of f_U) and $f(x, x) = 0$ because x is q -singular, whence f -isotropic. It follows that $f_U(x + U, x + U) = 0$ for every coset $x + U$. Thus, f_U is alternating. Moreover, for any vector $x \in V$ we have $f(x, x) = f_U(x + U, x + U)$ by definition of f_U and $f_U(x + U, x + U) = 0$ since f_U is alternating. Hence $f(x, x) = 0$ for every $x \in V$, namely f is alternating as well. Turning to S_q , two points $[x], [y] \in S_q$ are collinear in S_q if and only if $f(x, y) = 0$, equivalently $f_U(x + U, y + U) = 0$, namely $x + U$ and $y + U$ represent collinear points of S_{f_U} . Therefore π_U maps S_q isomorphically onto S_{f_U} , as claimed in (2). \square

4.2 Covers

4.2.1 Construction and properties of covers

Let $\overline{S} \oplus \overline{T} = \overline{R}$ be a direct sum decomposition of the K -vector space \overline{R} . Put $V^{\overline{S}} := V \oplus \overline{S}$ (direct sum of K -vector spaces). Define $f^{\overline{S}} : V^{\overline{S}} \times V^{\overline{S}} \rightarrow K$ as follows:

$$f^{\overline{S}}(x + \bar{r}, y + \bar{s}) = f(x, y) \quad \text{for all } x, y \in V \text{ and } \bar{r}, \bar{s} \in \overline{S}.$$

It is easy to see that $f^{\overline{S}}$ is a trace-valued (σ, ε) -sesquilinear form with $\text{Rad}(f^{\overline{S}}) = \text{Rad}(f) \oplus \overline{S}$. Clearly, f is isomorphic to the form induced by $f^{\overline{S}}$ on $V^{\overline{S}}/\overline{S} (\cong V)$.

Let $E = (e_i)_{i \in I}$ be a q -singular basis of V and let g_E be the facilitating form associated to E (see definition (24) in Subsection 3.3). We define a mapping $q_E^{\overline{S}, \overline{T}} : V^{\overline{S}} \rightarrow \overline{K}/\overline{T}$ as follows:

$$q_E^{\overline{S}, \overline{T}}(x + \bar{r}) = \overline{g_E(x, x)} + \bar{r} + \overline{T} \quad \text{for any } x \in V \text{ and any } \bar{r} \in \overline{S}.$$

In particular, $q_E^{\overline{S}, \overline{T}}(x) = \overline{g_E(x, x)} + \overline{T}$ and $q_E^{\overline{S}, \overline{T}}(\bar{r}) = \bar{r} + \overline{T}$.

Theorem 4.7 *The mapping $q_E^{\overline{S}, \overline{T}}$ is a non-trivial generalized (σ, ε) -quadratic form and $f^{\overline{S}}$ is its sesquilinearization.*

Proof. Let $x = \sum_i e_i \lambda_i$ and $\bar{r} \in \overline{S}$. According to the definition of $q_E^{\overline{S}, \overline{T}}$ we have

$$\begin{aligned} q_E^{\overline{S}, \overline{T}}((x + \bar{r})\lambda) &= q_E^{\overline{S}, \overline{T}}(x\lambda + \bar{r} \circ \lambda) = \sum_{i < j} \overline{\lambda^\sigma \lambda_i^\sigma f(e_i, e_j) \lambda_j \lambda} + \bar{r} \circ \lambda + \overline{T} = \\ &= \left(\sum_{i < j} \overline{\lambda_i^\sigma f(e_i, e_j) \lambda_j} \right) \circ \lambda + \bar{r} \circ \lambda + \overline{T} = q_E^{\overline{S}, \overline{T}}(x + \bar{r}) \circ \lambda. \end{aligned}$$

So, $q_E^{\overline{S}, \overline{T}}$ satisfies condition $(Q'1)$. Turning to $(Q'2)$, let $x = \sum_i e_i \lambda_i$, $y = \sum_i e_i \mu_i$ and $\bar{r}, \bar{s} \in \overline{S}$. Then

$$\begin{aligned} q_E^{\overline{S}, \overline{T}}((x + \bar{r}) + (y + \bar{s})) &= q_E^{\overline{S}, \overline{T}}((x + y) + (\bar{r} + \bar{s})) = \\ &= \sum_{i < j} \overline{f(e_i, e_j)} \circ (\lambda_j + \mu_j) + \bar{r} + \bar{s} + \overline{T}. \end{aligned} \tag{32}$$

On the other hand,

$$\begin{aligned} q_E^{\overline{S}, \overline{T}}(x + \bar{r}) + q_E^{\overline{S}, \overline{T}}(y + \bar{s}) &= \\ &= \sum_{i < j} \overline{f(e_i, e_j) \lambda_j} + \sum_{i < j} \overline{f(e_i, e_j) \mu_j} + \bar{r} + \bar{s} + \overline{T}. \end{aligned} \tag{33}$$

Moreover,

$$f^{\overline{S}}(x + \bar{r}, y + \bar{s}) = f(x, y) = \sum_{i < j} (\lambda_i^\sigma f(e_i, e_j) \mu_j). \tag{34}$$

By (32), (33) and (34) and recalling that

$$\begin{aligned} \mu_i^\sigma f(e_i, e_j) \lambda_j - \lambda_j^\sigma f(e_j, e_i) \mu_i &= \mu_i^\sigma f(e_i, e_j) \lambda_j - \lambda_j^\sigma f(e_i, e_j)^\sigma \varepsilon \mu_i = \\ &= \mu_i^\sigma f(e_i, e_j) \lambda_j - (\mu_i^\sigma f(e_i, e_j) \lambda_i)^\sigma \varepsilon \in K_{\sigma, \varepsilon} \end{aligned}$$

we obtain

$$\begin{aligned} q_E^{\overline{S}, \overline{T}}((x + \bar{r}) + (y + \bar{s})) - q_E^{\overline{S}, \overline{T}}(x + \bar{r}) - q_E^{\overline{S}, \overline{T}}(y + \bar{s}) - \overline{(f(x + \bar{r}, y + \bar{s}) + \overline{T})} &= \\ = \sum_{i < j} \overline{(\lambda_j^\sigma f(e_j, e_i) \mu_i + \lambda_i^\sigma f(e_i, e_j) \mu_j)} - \sum_{i, j} \overline{\lambda^\sigma f(e_i, e_j) \mu_j} + \overline{T} &= \\ = \sum_i \overline{\lambda_i^\sigma f(e_i, e_i) \mu_i} + \overline{T} = \overline{T}. \end{aligned}$$

(Recall that $f(e_i, e_i) = 0$ since $q(e_i) = 0_{\overline{R}}$ by assumption.) Finally,

$$q_E^{\overline{S}, \overline{T}}((x + \bar{r}) + (y + \bar{s})) - q_E^{\overline{S}, \overline{T}}(x + \bar{r}) - q_E^{\overline{S}, \overline{T}}(y + \bar{s}) - \overline{(f(x + \bar{r}, y + \bar{s}) + \overline{T})} = \overline{T}.$$

Property (Q'2) is proved. The non-triviality of $q_E^{\overline{S}, \overline{T}}$ immediately follows from the fact that q is non-trivial by assumption. \square

We say that $q_E^{\overline{S}, \overline{T}}$ is the *cover* of q via $(\overline{S}, \overline{T})$ based at E (a *cover* of q , for short). A motivation for this definition is given by the following theorem.

Theorem 4.8 *The subspace \overline{S} of $V^{\overline{S}}$ defines a quotient $(q_E^{\overline{S}, \overline{T}})_{\overline{S}}$ of $q_E^{\overline{S}, \overline{T}}$. With an obvious identification of $V^{\overline{S}}/\overline{S}$ with V , we have $(q_E^{\overline{S}, \overline{T}})_{\overline{S}} = q$.*

The proof is straightforward. We leave it to the reader. By combining this theorem with Theorem 4.6 we immediately obtain the following:

Corollary 4.9 *The polar space associated to $q_E^{\overline{S}, \overline{T}}$ in $\text{PG}(V^{\overline{S}})$ is isomorphic to the polar space S_q associated to q .*

Theorem 4.8 can be rephrased in the language of embeddings, but in view of that we need a few more definitions. For $\bar{r} \in \overline{R}$, let $\theta(\bar{r})$ be the projection of \bar{r} onto \overline{S} along \overline{T} , namely $\theta(\bar{r})$ is the unique element of $\overline{S} \cap (\bar{r} + \overline{T})$. For every q -singular vector $x \in V$, the subspace $\langle x, \overline{S} \rangle$ of $V^{\overline{S}}$ contains a unique $q_E^{\overline{S}, \overline{T}}$ -singular point, represented by the vector $x - \theta(\overline{g_E(x, x)})$. Put

$$e_{q, E}^{\overline{S}, \overline{T}}([x]) := [x - \theta(\overline{g_E(x, x)})]. \quad (35)$$

The following is straightforward. We leave its proof to the reader.

Theorem 4.10 *The mapping $e_{q, E}^{\overline{S}, \overline{T}}$ is a projective embedding of S_q in $\text{PG}(V^{\overline{S}})$. The image $e_{q, E}^{\overline{S}, \overline{T}}(S_q)$ of S_q by $e_{q, E}^{\overline{S}, \overline{T}}$ is the polar space associated to $q_E^{\overline{S}, \overline{T}}$ in $\text{PG}(V^{\overline{S}})$. Moreover, if $\pi_{\overline{S}}$ is the projection of $V^{\overline{S}}$ onto $V^{\overline{S}}/\overline{S}$, then the canonical isomorphism from $V^{\overline{S}}/\overline{S}$ to V yields an isomorphism from the composition $\pi_{\overline{S}} \cdot e_{q, E}^{\overline{S}, \overline{T}}$ to the inclusion embedding $e_q : S_q \rightarrow \text{PG}(V)$.*

We call $e_{q,E}^{\overline{S},\overline{T}}$ the *lifting* of e_q to $V^{\overline{S}}$ based at E .

Remark. We have assumed that q is non-trivial since the very beginning of Section 4, however the previous construction can be repeated when q is trivial. In that case we choose a sesquilinearization f of q and we define $q_E^{\overline{S},\overline{T}}$ with the help of f , as in the non-trivial case, but the form $q_E^{\overline{S},\overline{T}}$ now depends on the particular choice of f . The form $q_E^{\overline{S},\overline{T}}$ is non-trivial provided that $\overline{S} \neq \{\overline{0}\}$. It is still true that q is a quotient of $q_E^{\overline{S},\overline{T}}$, but Corollary 4.9 must be rephrased as follows: the polar space associated to $q_E^{\overline{S},\overline{T}}$ in $\text{PG}(V^{\overline{S}})$ is isomorphic to S_f (compare Theorem 4.6, (2)).

4.2.2 Independence of $q_E^{\overline{S},\overline{T}}$ from the choice of E

Our definition of $q_E^{\overline{S},\overline{T}}$ rests on the choice of a particular ordered q -singular basis E . In this subsection we shall prove that this choice is ultimately irrelevant: different choices lead to isomorphic forms.

Given two q -singular bases E and E' , let $\delta_{E,E'}$ be the difference-map of the pair (E, E') (see Subsection 3.3). Recall that $\delta_{E,E'}(x) \in \overline{R}_{E,E'} \subseteq \overline{R}$, by Lemma 3.10. Hence $\theta(\delta_{E,E'}(x))$ is defined for every $x \in V$, where θ is the projection of \overline{R} onto \overline{S} along \overline{T} , as in (35). In view of the definition of $\delta_{E,E'}$, the following holds for every vector $x \in V$:

$$x - \theta(\overline{g_{E'}(x, x)}) = x - \theta(\overline{g_E(x, x)}) + \theta(\delta_{E,E'}(x)).$$

Let $\Delta_{E,E'} : V^{\overline{S}} \rightarrow V^{\overline{S}}$ be the mapping defined as follows:

$$\Delta_{E,E'}(x + \bar{r}) = x + \theta(\delta_{E,E'}(x)) + \bar{r} \text{ for any } x \in V \text{ and } \bar{r} \in \overline{S}$$

Theorem 4.11 *The mapping $\Delta_{E,E'}$ is linear and bijective, it fixes \overline{S} element-wise and yields an isomorphism from $q_E^{\overline{S},\overline{T}}$ to $q_{E'}^{\overline{S},\overline{T}}$. Explicitly,*

$$q_E^{\overline{S},\overline{T}}(x + \bar{r}) = q_{E'}^{\overline{S},\overline{T}}(\Delta_{E,E'}(x + \bar{r})) \quad (36)$$

for any $x \in V$ and $\bar{r} \in \overline{S}$. Consequently, $\Delta_{E,E'}$ is an isomorphism of embeddings from the lifting $e_{q,E}^{\overline{S},\overline{T}}$ of e_q based at E to the lifting $e_{q,E'}^{\overline{S},\overline{T}}$ of e_q based at E' .

Proof. By Lemma 3.10, the difference-map $\delta_{E,E'}$ is a linear mapping from V to $\overline{R}_{E,E'}$. Hence $\Delta_{E,E'}$ is linear. Clearly, $\Delta_{E,E'}$ fixes \overline{S} elementwise. Moreover the composition of $\Delta_{E,E'}$ with the projection of $V^{\overline{S}}$ onto V along \overline{S} induces the identity mapping on V . Therefore $\Delta_{E,E'}$ is bijective. We have

$$\begin{aligned} q_E^{\overline{S},\overline{T}}(x + \bar{r}) &= \overline{g_E(x, x)} + \bar{r} + \overline{T} = \\ &= \overline{g_{E'}(x, x)} + (\overline{g_E(x, x)} - \overline{g_{E'}(x, x)}) + \bar{r} + \overline{T} = \\ &= \overline{g_{E'}(x, x)} + \delta_{E,E'}(x) + \bar{r} + \overline{T} = \end{aligned}$$

$$= \overline{g_{E'}(x, x)} + \theta(\delta_{E, E'}(x)) + \bar{r} + \bar{T} = q_{E'}^{\bar{S}, \bar{T}}.$$

(Recall that $\delta_{E, E'}(x) + \bar{T} = \theta(\delta_{E, E'}(x)) + \bar{T}$, by the definition of θ .) Equation (36) is proved. Exploiting (36), it is not difficult to prove that $\Delta_{E, E'}$ is an isomorphism from $e_{q, E}^{\bar{S}, \bar{T}}$ to $e_{q, E'}^{\bar{S}, \bar{T}}$. \square

Theorem 4.11 allows us to drop the index E in our notations, thus writing $q^{\bar{S}, \bar{T}}$ and $e_q^{\bar{S}, \bar{T}}$ for $q_E^{\bar{S}, \bar{T}}$ and $e_{q, E}^{\bar{S}, \bar{T}}$ whenever the particular choice of the basis E is irrelevant for what we are saying. Accordingly, we may call $q^{\bar{S}, \bar{T}}$ and $e_q^{\bar{S}, \bar{T}}$ the *cover* of q via (\bar{S}, \bar{T}) and the *lifting* of e_q to $V^{\bar{S}}$ respectively, with no mention of the basis E .

4.2.3 Dominant covers

As $\bar{S} \oplus \bar{T} = \bar{R}$, we have $\bar{S} = \bar{R}$ if and only if $\bar{T} = \{\bar{0}\}$. When $\bar{T} = \{\bar{0}\}$ the form $q^{\bar{S}, \bar{T}} = q^{\bar{R}, \{\bar{0}\}}$ is pseudo-quadratic with defect equal to $\text{Rad}(f) \oplus \bar{R}$.

Improper covers are allowed too. We get them by taking $\bar{S} = \{\bar{0}\}$ (whence $\bar{T} = \bar{R}$). Clearly, $q^{\{\bar{0}\}, \bar{R}} = q$.

Notice that we have not assumed that $\bar{R} \neq \{\bar{0}\}$. Indeed the construction of $q^{\bar{S}, \bar{T}}$ makes sense even if $\bar{R} = \{\bar{0}\}$, namely q is pseudo-quadratic. In this case $\bar{S} = \bar{T} = \{\bar{0}\}$, hence $q^{\bar{S}, \bar{T}} = q$, namely q does not admit any proper cover. Conversely, if q does not admit any proper cover then $\bar{R} = \{\bar{0}\}$.

We say that q is *dominant* if it does not admit any proper cover. By the above, q is dominant if and only if it is pseudo-quadratic. So, the form $q^{\bar{S}, \bar{T}}$ is dominant if and only if $\bar{T} = \{\bar{0}\}$. We call $q^{\bar{R}, \{\bar{0}\}}$ the *dominant cover* of q .

4.2.4 Quotients versus covers

According to Theorem 4.8, if $\tilde{q} : \tilde{V} \rightarrow \bar{K}/\bar{T}$ is a cover of $q : V \rightarrow \bar{K}/\bar{R}$ then q is a quotient of \tilde{q} . A converse of this statement also holds.

Theorem 4.12 *Given a subspace \bar{T} of \bar{K}° and a generalized (σ, ε) -quadratic form $\tilde{q} : \tilde{V} \rightarrow \bar{K}/\bar{T}$, let U be a subspace of \tilde{V} defining a quotient of \tilde{e} . Then \tilde{q} is isomorphic to a cover of the quotient \tilde{q}_U of \tilde{q} by U .*

Proof. Put $V := \tilde{V}/U$ and $q := \tilde{q}_U : V \rightarrow \bar{K}/\bar{R}$, where $\bar{R} := \bar{T}_U$ is the subspace of \bar{K}° such that $\bar{R}/\bar{T} = \tilde{q}(U)$ (see Subsection 4.1). Let \bar{S} be a complement of \bar{T} in the K -vector space \bar{R} , let W be a complement of U in \tilde{V} , let π_U be the projection of \tilde{V} onto $V = \tilde{V}/U$ and θ the projection of \bar{R} onto \bar{S} along \bar{T} . Let $\alpha : \tilde{V} \rightarrow V^{\bar{S}} = V \oplus \bar{S}$ be the linear mapping defined by the following clauses: $\alpha(w) = \pi_U(w)$ for every $w \in W$ and $\alpha(u) = \theta(\tilde{q}(u))$ for every $u \in U$. As the reader can check, α is an isomorphism from \tilde{q} to $q^{\bar{S}, \bar{T}}$. \square

Corollary 4.13 *Let $q : V \rightarrow \overline{K}/\overline{R}$ be a non-trivial generalized (σ, ε) -quadratic form. Given a vector subspace \overline{T} of \overline{R} , let \overline{S} and \overline{S}' be two complements of \overline{T} in \overline{R} . Then $q^{\overline{S}, \overline{T}} \cong q^{\overline{S}', \overline{T}}$.*

Proof. The conclusion follows from the proof of Theorem 4.12 with $V^{\overline{S}'}$, $q^{\overline{S}', \overline{T}}$ and \overline{S}' in the roles of \tilde{V} , \tilde{q} and U respectively, recalling that q is the quotient of $q^{\overline{S}', \overline{T}}$ over \overline{S}' by Theorem 4.8. \square

4.2.5 Partial independence of $q^{\overline{S}, \overline{T}}$ from the choice of \overline{S} and \overline{T}

In general, if $\overline{R} = \overline{S} \oplus \overline{T}$ and $\overline{R} = \overline{S}' \oplus \overline{T}'$ are two decompositions of \overline{R} then $q^{\overline{S}, \overline{T}} \not\cong q^{\overline{S}', \overline{T}'}$. However, with a suitable choice of \overline{T}' the forms $q^{\overline{S}, \overline{T}}$ and $q^{\overline{S}', \overline{T}'}$ are weakly isomorphic in the sense of Subsection 3.4. Explicitly:

Proposition 4.14 *With $\overline{S}, \overline{T}, \overline{S}'$ and \overline{T}' as above, suppose that K admits an automorphism ρ stabilizing (σ, ε) and such that the automorphism $\bar{\rho}$ of \overline{K} induced by ρ stabilizes \overline{R} and maps \overline{T} onto \overline{T}' . Then the forms $q^{\overline{S}, \overline{T}}$ and $q^{\overline{S}', \overline{T}'}$ are weakly isomorphic.*

Proof. Given a q -singular basis E of V let ρ_E be the ρ -semi-linear mapping of V that fixes all vectors of E and, for $x \in V$ and $\bar{r} \in \overline{S}$, set $\rho_E(x + \bar{r}) := \rho_E(x) + \bar{r}^{\bar{\rho}}$. Then ρ_E is a bijective ρ -semilinear mapping from $V^{\overline{S}}$ to $V^{\overline{S}'}$ and we have

$$(q^{\overline{S}, \overline{T}}(x + \bar{r}))^{\bar{\rho}} = q^{\overline{S}', \overline{T}'}(\rho_E(x + \bar{r}))$$

for every vector $x + \bar{r}$ of $V^{\overline{S}}$. Hence $q^{\overline{S}, \overline{T}}$ and $q^{\overline{S}', \overline{T}'}$ are weakly isomorphic. However $q^{\overline{S}', \overline{T}'} \cong q^{\overline{S}', \overline{T}'}$ by Corollary 4.13 and because $\overline{R}^{\bar{\rho}} = \overline{R}$ and $\overline{T}^{\bar{\rho}} = \overline{T}'$ by assumption. Therefore $q^{\overline{S}, \overline{T}}$ and $q^{\overline{S}', \overline{T}'}$ are weakly isomorphic. \square

5 Forms for embedded polar spaces

Throughout this section $S = (P, L)$ is a non-degenerate polar space of rank at least 2 and $e : S \rightarrow \text{PG}(V)$ is a projective embedding. So, the image $e(S) = (e(P), e(L))$ of S by e is a full subgeometry of $\text{PG}(V)$, it spans $\text{PG}(V)$ and $e(S) \cong S$.

Let K be the underlying division ring of V . By Theorem 1.1, an admissible pair (σ, ε) of K and a (σ, ε) -sesquilinear form $f : V \times V \rightarrow K$ exist such that $e(S)$ is a subspace of the polar space $S_f = (P_f, L_f)$ associated to f . Explicitly,

- (E1) $e(P) \subseteq P_f$ and, for any two points $[x], [y] \in e(P)$, the line $[x, y]$ of $\text{PG}(V)$ belongs to $e(L)$ if and only if $f(x, y) = 0$.

Property (E1) implies both the following:

- (E2) For any two points $[x]$ and $[y]$ of $\text{PG}(V)$ with $[y] \in e(P)$, we have $f(x, y) = 0$ if and only if either the line $[x, y]$ belongs to $e(L)$ or $[x, y] \cap e(P) = \{[y]\}$.

(E3) $e(P) \cap [\text{Rad}(f)] = \emptyset$.

As for (E3), recall that S is non-degenerate by assumption while f might be degenerate. By (E1), (E2) and (E3) and recalling that $e(P)$ spans $\text{PG}(V)$, we also obtain the following:

(E4) A point $[x]$ of $\text{PG}(V)$ belongs to $[\text{Rad}(f)]$ if and only if every line of $\text{PG}(V)$ through $[x]$ meets $e(P)$ in at most one point.

The form f is uniquely determined up to proportionality (Proposition 2.6). Moreover f is trace-valued by (2) of Proposition 2.5, since $P_f \supseteq e(P)$ and $e(P)$ spans $\text{PG}(V)$.

Let $E = (e_i)_{i \in I}$ be a basis of V such that $[e_i] \in e(P)$ for any $i \in I$. Such a basis exists since $e(P)$ spans $\text{PG}(V)$. We call E an $e(S)$ -basis of V . Given a total ordering $<$ on I , let $g_E(x, y)$ be defined as in (24) of Subsection 3.3 and put

$$\gamma_E(x) := \overline{g_E(x, x)} = \sum_{i < j} \overline{\lambda_i^\sigma f(e_i, e_j) \lambda_j} \quad \text{for every vector } x = \sum_i e_i \lambda_i \in V.$$

Lemma 5.1 *The mapping γ_E is a (possibly trivial) (σ, ε) -quadratic form, g_E is a facilitating form for γ_E and f is a sesquilinearization of γ_E . The form γ_E is trivial if and only if $\sigma = \text{id}_K$, $\varepsilon = -1$ and $\text{char}(K) \neq 2$.*

Proof. The first three claims of the lemma are obvious (compare Subsection 2.3.1). The last one follows from the second part of (3) of Subsection 2.1. \square

Let \overline{R} be the closed subgroup of \overline{K} generated by the set $\{\gamma_E(x)\}_{[x] \in e(P)}$ and define a mapping $q : V \rightarrow \overline{K}/\overline{R}$ as follows:

$$q(x) := \gamma_E(x) + \overline{R}. \quad (37)$$

The next lemma easily follows from Lemma 5.1 and the definition of \overline{R} .

Lemma 5.2 *The mapping q defined in (37) is a (possibly trivial) generalized (σ, ε) -quadratic form. If q is non-trivial then f is the sesquilinearization of q . In this case $e(S)$ is a subspace of the polar space $S_q = (P_q, L_q)$ associated to q .*

Proof. The first two claims of the lemma are straightforward. As for the third one, note firstly that S_q is a subspace of S_f since f is the sesquilinearization of q by Lemma 5.2. Clearly, $e(P) \subseteq P_q$. Therefore $e(S)$ is a subspace of S_q , as both $e(S)$ and S_q are subspaces of S_f . \square

Corollary 5.3 *If (σ, ε) is of trace type then either $\overline{R} = \overline{K}$ or $\overline{R} = \{\overline{0}\}$.*

Proof. This statement easily follows from Lemma 5.2 and Corollary 3.3. \square

Note that, while γ_E depends on the choice of the ordered basis E , neither \overline{R} nor q depend on that choice (see the final remark of Subsection 3.3).

Corollary 5.4 *The form q is trivial if and only if $\overline{R} = \overline{K}$. If γ_E is trivial then $\overline{R} = \overline{K}$ (whence q is also trivial)*

Proof. The form f is non-trivial, since $e(S)$ is a subspace of S_f and it is non-degenerate. This fact and Proposition 3.4 imply the first claim of the corollary. According to the last claim of Lemma 5.1, the form γ_E is trivial if and only if f is alternating and $\text{char}(K) \neq 2$. If this is the case then $\overline{R} = \overline{K}$. \square

Theorem 5.5 *Either q is trivial or $e(S) = S_q$.*

Proof. Suppose that q is non-trivial. By Corollary 5.4, \overline{R} is a proper subgroup of \overline{K} . Moreover $e(S)$ is a subspace of S_q , by the last claim of Lemma 5.2.

Let $\tilde{q} := q^{\overline{R}, \{0\}} : V \oplus \overline{R} \rightarrow \overline{K}$ be the dominant cover of q based at E , let $\tilde{f} := f^{\overline{R}}$ be the sesquilinearization of \tilde{q} and put $\tilde{V} = V \oplus \overline{R}$. Clearly, if $\overline{R} = \{0\}$ (as when (σ, ε) is of trace type) then $\tilde{q} = q$, $\tilde{f} = f$ and $\tilde{V} = V$.

The embedding $e : S \rightarrow \text{PG}(V)$ lifts to an embedding $\tilde{e} : S \rightarrow \text{PG}(\tilde{V})$, obtained as the composition of e with the lifting of the inclusion embedding $e_q : S_q \rightarrow \text{PG}(V)$ to \tilde{V} (see definition (35) of Subsection 4.2.1). Let \hat{V} be the subspace of \tilde{V} spanned by $\tilde{e}(P)$. We shall prove that $\hat{V} = \tilde{V}$.

Put $\hat{R} := \overline{R} \cap \hat{V}$ and let \hat{q} and \hat{f} be the forms induced by \tilde{q} and \tilde{f} on \hat{V} . Clearly, all points of $\tilde{e}(P)$ are \hat{q} -singular. As $\hat{V} + \overline{R} = \tilde{V}$, we have $\hat{V}/\hat{R} \cong \tilde{V}/\overline{R} \cong V$ and \hat{R} defines a quotient $\hat{q}_{\hat{R}}$ of \hat{q} . Via an obvious identification of V with \hat{V}/\hat{R} , we may assume that $\hat{q}_{\hat{R}}$ is defined over V . Accordingly, all points of $e(P)$ are $\hat{q}_{\hat{R}}$ -singular. It follows that $\gamma_E(x)$ belongs to the co-defect \hat{R} of $\hat{q}_{\hat{R}}$, for every point $[x] \in e(P)$. However, \overline{R} is generated by $\{\gamma(x)\}_{[x] \in e(P)}$. Therefore $\hat{R} = \overline{R}$. Hence $\overline{R} \subseteq \hat{V}$. It is now clear that $\hat{V} = \tilde{V}$, namely $\tilde{e}(P)$ spans $\text{PG}(\tilde{V})$.

Since $e(S)$ is a subspace of S_q , the image $\tilde{e}(S)$ of S by \tilde{e} is a subspace of the polar space $S_{\tilde{q}} = (P_{\tilde{q}}, L_{\tilde{q}})$ associated to \tilde{q} . The latter is a subspace of the polar space $S_{\tilde{f}} = (P_{\tilde{f}}, L_{\tilde{f}})$ associated to \tilde{f} . Hence $\tilde{e}(S)$ is also a subspace of $S_{\tilde{f}}$, namely (E1) holds with $\tilde{e}(S)$ and \tilde{f} in the roles of $e(S)$ and f respectively. Consequently, properties (E2), (E3) and (E4) also hold for $\tilde{e}(S)$ and \tilde{f} .

We shall now prove that $e(S) = S_q$. Suppose the contrary, namely $e(P) \subset P_q$. Then we also have $\tilde{e}(P) \subset P_{\tilde{q}}$. Let $[a] \in P_{\tilde{q}} - \tilde{e}(P)$. Suppose firstly that $[a] \notin [\text{Rad}(\tilde{f})]$. By (E4), there exist two distinct points $[b], [c] \in \tilde{e}(P)$ such that the line $[b, c]$ contains $[a]$. We have $\tilde{f}(a, a) = \tilde{f}(b, c) = \tilde{f}(c, c) = 0$ since all of $[a], [b]$ and $[c]$ belong to $P_{\tilde{f}}$. On the other hand, the line $[b, c]$ does not belong to $\tilde{e}(L)$, since it contains $[a]$ which, by assumption, does not belong to $\tilde{e}(P)$. Then $\tilde{f}(b, c) \neq 0$ by (E1). Since $\tilde{f}(b, b) = \tilde{f}(c, c) = 0$ while $\tilde{f}(b, c) \neq 0$, the form \tilde{f} induces a non-degenerate form on the subspace $\langle b, c \rangle$ of \tilde{V} . Thus we can apply Proposition 10.3.10 of Buekenhout and Cohen [1]. By claim (i) of that proposition, $P_{\tilde{q}} \cap [b, c]$ is the smallest subset of $S_{\tilde{f}} \cap [b, c]$ containing $[b]$ and $[c]$ and perspective with respect to the polarity $\delta_{\tilde{f}, [b, c]}$ defined by \tilde{f} on the line $[b, c]$. However, $[b], [c] \in \tilde{e}(P) \cap [b, c] \subseteq P_{\tilde{q}} \cap [b, c]$ and $\tilde{e}(P) \cap [b, c]$ is also perspective with respect to $\delta_{\tilde{f}, [b, c]}$ by Proposition 10.3.4 of Buekenhout and

Cohen [1]. Hence $\tilde{e}(P) \cap [b, c] = P_{\tilde{q}} \cap [b, c]$. In particular, $[a] \in \tilde{e}(P)$, contrary to our choice of $[a]$. Therefore $[a] \in [\text{Rad}(\tilde{f})]$, namely $[a] \in [\text{Rad}(\tilde{q})]$, as $[a] \in P_{\tilde{q}}$. It follows that $P_{\tilde{q}} - \tilde{e}(P) \subseteq [\text{Rad}(\tilde{q})]$.

Still with $[a] \in P_{\tilde{q}} - \tilde{e}(P) \subseteq [\text{Rad}(\tilde{q})]$, let $[b] \in \tilde{e}(P)$. As both $[b]$ and $[a]$ are \tilde{q} -singular and $[a] \in [\text{Rad}(\tilde{q})]$, the line $[a, b]$ belongs to $L_{\tilde{q}}$. Hence it is totally \tilde{f} -isotropic. By (E1), if $[a, b]$ contains a point of $\tilde{e}(P)$ different from $[b]$ then it also belongs to $\tilde{e}(L)$, but this contradicts the choice of $[a] \in P_{\tilde{q}} - \tilde{e}(P)$. Therefore $[a, b] \cap \tilde{e}(P) = \{[b]\}$, namely $[a, b] - \{[b]\} \subseteq P_{\tilde{q}} - \tilde{e}(P)$. However $P_{\tilde{q}} - \tilde{e}(P) \subseteq [\text{Rad}(\tilde{q})]$ and the latter is a subspace of $\text{PG}(\tilde{V})$. It follows that $[a, b] \subseteq [\text{Rad}(\tilde{q})]$. This forces $[b] \in [\text{Rad}(\tilde{q})] \cap \tilde{e}(P) \subseteq [\text{Rad}(\tilde{f})] \cap \tilde{e}(P)$, a contradiction with (E3). We have reached a final contradiction. Therefore $e(S) = S_q$. \square

Let $\overline{R} \neq \overline{K}$. Then both q and γ_E are non-trivial (Corollary 5.4). Let $S_{\gamma_E} = (P_{\gamma_E}, L_{\gamma_E})$ be the polar space associated to γ_E in $\text{PG}(V)$. Clearly, S_{γ_E} is a subspace of S_f .

Corollary 5.6 *Let $\overline{R} \neq \overline{K}$. Then S_{γ_E} is a subspace of $e(S)$. If moreover (σ, ε) is of trace type then $S_{\gamma_E} = e(S) = S_f$.*

Proof. Clearly S_{γ_E} is a subgeometry of S_q . Moreover both S_{γ_E} and S_q are subspaces of S_f . Hence S_{γ_E} is a subspace of S_q . However $S_q = e(S)$ by Theorem 5.5. Therefore S_{γ_E} is a subspace of $e(S)$.

Let (σ, ε) be of trace type. Then $S_{\gamma_E} = S_f$ by Proposition 2.14. Hence $S_{\gamma_E} = e(S) = S_f$, since S_{γ_E} is a subspace of $e(S) = S_q$ which in its turn is a subspace of S_f . \square

Remark. When (σ, ε) is not of trace type it can happen that S_{γ_E} is a proper subspace of $e(S)$. If that is the case then the space S_{γ_E} depends on the choice of the $e(S)$ -basis E .

Theorem 5.7 *Let $\overline{R} = \overline{K}$. Then f is an alternating form and $e(S) = S_f$.*

Proof. As $\overline{R} = \overline{K}$, the group \overline{K} is generated by the elements $\gamma_E(x)$ for $[x] \in e(S)$. However $e(S)$ is a subspace of S_f . Hence \overline{K} is also generated by the elements $\gamma_E(x)$ for x such that $f(x, x) = 0$.

Given $x = \sum_i e_i \lambda_i$, let $t := \sum_{i < j} \lambda_i^\sigma f(e_i, e_j) \lambda_j$. Then

$$f(x, x) = \sum_{i, j} \lambda_i^\sigma f(e_i, e_j) \lambda_j = \sum_{i \neq j} \lambda_i^\sigma f(e_i, e_j) \lambda_j + \sum_i \lambda_i^\sigma f(e_i, e_i) \lambda_i.$$

However $f(e_i, e_i) = 0$ for every $i \in I$ because $[e_i] \in e(P) \subseteq P_f$. Therefore

$$\begin{aligned} 0 &= \sum_{i \neq j} \lambda_i^\sigma f(e_i, e_j) \lambda_j = \sum_{i < j} \lambda_i^\sigma f(e_i, e_j) \lambda_j + \sum_{i > j} \lambda_i^\sigma f(e_i, e_j) \lambda_j = \\ &= \sum_{i < j} \lambda_i^\sigma f(e_i, e_j) \lambda_j + \sum_{j > i} \lambda_j^\sigma f(e_j, e_i) \lambda_i = \\ &= \sum_{i < j} \lambda_i^\sigma f(e_i, e_j) \lambda_j + \sum_{i < j} (\lambda_i^\sigma f(e_i, e_j) \lambda_j)^\sigma \varepsilon = \\ &= \sum_{i < j} \lambda_i^\sigma f(e_i, e_j) \lambda_j + (\sum_{i < j} \lambda_i^\sigma f(e_i, e_j) \lambda_j)^\sigma \varepsilon = t + t^\sigma \varepsilon. \end{aligned}$$

Hence $f(x, x) = 0$ if and only if $t = -t^\sigma \varepsilon$, namely $t \in K^{\sigma, \varepsilon}$. However \overline{K} is generated by the values $\gamma_E(x)$ with $f(x, x) = 0$. Therefore $K = K^{\sigma, \varepsilon}$. The latter holds precisely when $\varepsilon = -1$ and $\sigma = \text{id}_K$, by the first claim of (3) of Subsection 2.1.

So, $\sigma = \text{id}_K$ and $\varepsilon = -1$. In particular, K is a field. If $\text{char}(K) \neq 2$ then f is alternating. Let $\text{char}(K) = 2$. Then f is a symmetric bilinear form. However, f is also trace-valued. It is well known that the alternating forms are the only trace-valued symmetric bilinear forms in characteristic 2. Hence f is alternating.

We still must prove that $e(S) = S_f$. This can be proved with the help of Theorem 1.2, but according to the philosophy we have chosen in this paper, we prefer not to use that theorem.

We firstly assume that $\text{char}(K) \neq 2$. By way of contradiction, suppose that $P_f \not\subseteq e(P)$ and let $[a] \in P_f - e(P)$. Assume that $[a] \notin [\text{Rad}(f)]$. By (E4), there exists at least one line l of $\text{PG}(V)$ containing $[a]$ and intersecting $e(P)$ in at least two points. By Proposition 10.3.4 of Buekenhout and Cohen [1], the set $e(P) \cap l$ is perspective with respect to the polarity $\delta_{f, l}$ defined by f on the line l . However, according to Buekenhout and Cohen [1, Proposition 10.3.10(ii)], the line l does not contain any proper subset of size at least two and perspective with respect to $\delta_{f, l}$. Therefore $l = e(P) \cap l$. This contradicts the choice of $[a] \notin e(P)$. We must conclude that $[a] \in [\text{Rad}(f)]$. So, $P_f - e(P) \subseteq [\text{Rad}(f)]$. With $[a] \in P_f - e(P) \subseteq [\text{Rad}(f)]$, let $[b] \in e(P)$. Then $[a, b] \cap e(P) = \{[b]\}$ by (E1). Consequently $[a, b] - \{[b]\} \subseteq [\text{Rad}(f)]$. However $\text{Rad}(f)$ is a subspace of V . Hence $[b] \in [\text{Rad}(f)]$, in contradiction with (E3). Therefore $e(S) = S_f$.

Let now $\text{char}(K) = 2$. Then $K_{\sigma, \varepsilon} = 0$, $K^{\sigma, \varepsilon} = K$ and $\overline{K} = \overline{K}^\circ = K$. In particular, the scalar multiplication \circ is defined over K and $t \circ \lambda = t\lambda^2$ for any $t, \lambda \in K$. The additive group of K equipped with \circ as the scalar multiplication is a K -vector space. In order to distinguish between this vector space and the field K itself we denote the latter by the letter K , keeping the symbol \overline{K} for the vector space structure (K, \circ) . Given an element $t \in K$, if we regard it as a vector of \overline{K} then we write \bar{t} rather than t .

Put $\tilde{V} := V \oplus \overline{K}$. The set $W := \{x + \overline{\gamma_E(x)}\}_{[x] \in e(P)}$ is a subset of \tilde{V} and contains E . However E spans V , the latter being now regarded as a subspace of \tilde{V} . Therefore $\langle W \rangle \supseteq V$. It follows that $\langle W \rangle$ also contains the set $\{\overline{\gamma_E(x)}\}_{[x] \in e(P)}$. The latter spans \overline{R} and $\overline{R} = \overline{K}$, by assumption. Therefore W spans \tilde{V} . We now define a quadratic form \tilde{q} and an alternating form \tilde{f} on \tilde{V} , as follows:

$$\tilde{q}(x + \bar{t}) = \gamma_E(x) + t \quad \text{for any } x \in V \text{ and } \bar{t} \in \overline{K}.$$

$$\tilde{f}(x + \bar{t}, y + \bar{s}) = f(x, y) \quad \text{for any } x, y \in V \text{ and } \bar{t}, \bar{s} \in \overline{K}.$$

It is readily seen that \tilde{q} is indeed a quadratic form and \tilde{f} is its sesquilinearization. Note that $\text{Rad}(f) = \overline{K}$ and \overline{K} contains no \tilde{q} -singular point. Hence \tilde{q} is non-singular. Accordingly, the polar space $S_{\tilde{q}} = (P_{\tilde{q}}, L_{\tilde{q}})$ associated to \tilde{q} in $\text{PG}(\tilde{V})$ is non-degenerate. Moreover $S_{\tilde{q}}$ is a subspace of the polar space $S_{\tilde{f}}$ associated to \tilde{f} , as \tilde{f} is the sesquilinearization of \tilde{q} .

For $x \in V$ and $\bar{t} \in \overline{K}$ we have $\tilde{q}(x + \bar{t}) = 0$ if and only if $t = \gamma_E(x)$. Hence the set $\tilde{P} := \{[v]\}_{v \in W}$ is contained in $P_{\tilde{q}}$. It is not difficult to see that \tilde{P} is a subspace of $S_{\tilde{q}}$. Let \tilde{S} be the polar space induced by $S_{\tilde{q}}$ on \tilde{P} . Clearly, \tilde{S} is a subspace of $S_{\tilde{q}}$. Hence it is also a subspace of $S_{\tilde{f}}$, since $S_{\tilde{q}}$ is a subspace of $S_{\tilde{f}}$. Since \tilde{P} spans \tilde{V} and \tilde{S} is a subspace of $S_{\tilde{q}}$, the radical of \tilde{S} is contained in the radical of $S_{\tilde{q}}$. However $S_{\tilde{q}}$ is non-degenerate. Hence \tilde{S} is non-degenerate. Consequently, property (E1) (whence (E2), (E3) and (E4)) hold for \tilde{S} and \tilde{f} .

We shall prove that $\tilde{S} = S_{\tilde{q}}$. By way of contradiction, let $[a] \in P_{\tilde{q}} - \tilde{P}$. Note that $a \notin \text{Rad}(\tilde{f})$, because $S_{\tilde{q}}$ is non-degenerate. Then, by (E4) applied to \tilde{S} and \tilde{f} , there is a line l of $\text{PG}(\tilde{V})$ containing $[a]$ and two distinct points $[b], [c] \in \tilde{P}$. The line l belongs to $L_{\tilde{q}}$, since it contains at least three distinct points of $P_{\tilde{q}}$ and \tilde{q} is quadratic. Consequently, l is totally singular for \tilde{q} . Hence l is also totally isotropic for \tilde{f} . In particular $f(b, c) = 0$. This forces l to be a line of \tilde{S} too, a contradiction with the choice of $[a] \notin \tilde{P}$. Therefore $\tilde{S} = S_{\tilde{q}}$.

The projection $\pi_{\overline{K}} : \tilde{V} \rightarrow \tilde{V}/\overline{K} = V$ induces an isomorphism from \tilde{S} to $e(S)$. On the other hand, the quotient $\tilde{q}_{\overline{K}}$ of \tilde{q} by \overline{K} is trivial. Hence $\pi_{\overline{K}}$ induces an isomorphism from $S_{\tilde{q}}$ to S_f , by claim (2) of Theorem 4.6. However $S_{\tilde{q}} = \tilde{S}$. Therefore $e(S) = S_f$. \square

6 Initial embeddings

In this section we shall revisit Theorem 1.2, giving an elementary proof the fact that the embeddings considered in Theorem 1.2 are dominant and a proof of the last claim of Theorem 1.2 in the case of rank at least 3, different from the original proof of Tits [7].

With $e : S \rightarrow \text{PG}(V)$ and $f : V \times V \rightarrow K$ as in the previous section, let $q : V \rightarrow \overline{K}/\overline{R}$ be the generalized pseudo-quadratic form defined as in (37). By Theorems 5.5 and 5.7, either q is non-trivial and $e(S) = S_q$ or K is a field, f is alternating and $e(S) = S_f$.

The existence of the cover $q^{\overline{R}, \{\bar{0}\}}$ makes it clear that, if $e(S) = S_q$, then e is dominant only if $\overline{R} = \{\bar{0}\}$, namely q is pseudo-quadratic. Conversely,

Lemma 6.1 *Suppose that either q is pseudo-quadratic or f is alternating and $\text{char}(K) \neq 2$. Then e is dominant.*

Proof. This lemma is contained in Theorem 1.2 but, since we are revisiting Theorem 1.2, we shall give a proof independent of that theorem. Our proof exploits Theorems 5.5 and 5.7 and properties of quotients of generalized pseudo-quadratic forms.

Let $\tilde{e} : S \rightarrow \text{PG}(\tilde{V})$ be the hull of e . Then there exists a reflexive sesquilinear form $\tilde{f} : \tilde{V} \times \tilde{V} \rightarrow K$ such that $\tilde{e}(S)$ is a subspace of $S_{\tilde{f}}$. Let $\tilde{q} : \tilde{V} \rightarrow \overline{K}/\overline{R}$ be the generalized pseudo-quadratic form defined as in (37) but with V and f replaced with \tilde{V} and \tilde{f} respectively. By Theorems 5.5 and 5.7, either $\overline{R} \subset \overline{K}$ and $\tilde{e}(S) = S_{\tilde{q}}$ or $\overline{R} = \overline{K}$ and $\tilde{e}(S) = S_{\tilde{f}}$.

As \tilde{e} is the hull of e , there exists a subspace U of $\text{Rad}(\tilde{f})$ such that $e \cong \tilde{e}/U$. If $\tilde{e}(S) = S_{\tilde{f}}$ then \tilde{f} is non-degenerate. In this case $U = \{0\}$, whence $e \cong \tilde{e}$, namely e is dominant.

Suppose that $\overline{R} \subset \overline{K}$. Then $\tilde{e}(S) = S_{\tilde{q}}$ and $e(S) = S_{\tilde{q}_U}$, where \tilde{q}_U is the quotient of \tilde{q} by U , regarded as a generalized pseudo-quadratic form on V via an obvious identification of V with \tilde{V}/U . Then q and \tilde{q}_U are proportional, by Theorem 3.11. Hence \tilde{q}_U is a pseudo-quadratic form. However pseudo-quadratic forms do not admit proper covers (Subsection 4.2.3), while \tilde{q} is a cover of \tilde{q}_U by Theorem 4.12. Hence $\tilde{q}_U \cong \tilde{q}$, namely $U = \{0\}$. Again, $e \cong \tilde{e}$. \square

Turning back to the general case, when $\overline{R} \subset \overline{K}$ we denote by \tilde{e} the composition of e with the lifting of $e_q : S_q \rightarrow \text{PG}(V)$ to $\tilde{V} := V^{\overline{R}}$. Thus, $\tilde{e}(S) = S_{\tilde{q}}$, where $\tilde{q} := q^{\overline{R}, \{0\}}$ is the dominant cover of q , as in the proof of Theorem 5.5. When $\overline{R} = \overline{K}$ and $\text{char}(K) \neq 2$ we set $\tilde{V} := V$ and $\tilde{e} := e$. Finally, let $\overline{R} = \overline{K}$ but $\text{char}(K) = 2$. It is well known that in this case e is a quotient of an embedding $\tilde{e} : S \rightarrow \text{PG}(\tilde{V})$, where $\tilde{e}(S) = S_{\tilde{q}}$ for a suitable quadratic form $\tilde{q} : \tilde{V} \rightarrow K$ (see e.g. De Bruyn and Pasini [4]).

Theorem 6.2 *In each of the cases considered above the embedding \tilde{e} is dominant, whence it is the hull of e .*

Proof. This statement immediately follows from Lemma 6.1, recalling that dominant covers of generalized pseudo-quadratic forms are pseudo-quadratic forms (Subsection 4.2.3). \square

Corollary 6.3 *With \tilde{e} as above, assume moreover that S has rank at least 3. Then \tilde{e} is absolutely initial.*

Proof. Embeddable polar spaces of rank at least 3 satisfy the conditions of the main theorem of Kasikova and Shult [5], which are sufficient for the existence of a K -initial embedding. Therefore the embedding \tilde{e} , being dominant, is also K -initial (see Subsection 1.3.3). On the other hand, since K is the division ring coordinatizing the planes of S , all projective embeddings of S are K -embeddings, namely S is defined over K . Hence \tilde{e} is absolutely initial. \square

The statement of Corollary 6.3 is included in Theorem 1.2, which is a rephrasing of Theorem 8.6 of Tits [7], but the proof given by Tits for Theorem 8.6 of [7] is rather different from our proof of Corollary 6.3. In our proof we rely on the main result of Kasikova and Shult [5], which can be applied to polar spaces of rank at least 3 thanks to the fact that the maximal singular subspaces of such a polar space are projective spaces of dimension at least 2, while the proof given by Tits in [7] relies on certain deep properties of projective lines. Tits's proof also applies to polar spaces of rank 2 but for the two exceptional cases described in the following theorem (and mentioned in Theorem 1.2).

Theorem 6.4 [Tits [7, 8.6]] *The embedding \tilde{e} is absolutely initial even if S has rank 2, except in the following two cases:*

- (1) S is a grid and $|K| > 4$.
- (2) K is a quaternion division ring, $\tilde{V} = V(4, K)$ and, modulo proportionality and isomorphisms, $\varepsilon = -1$, σ is the standard involution of K , we have $K_{\sigma, \varepsilon} = Z(K)$ and $\tilde{q}(x_1, x_2, x_3, x_4) = x_1^\sigma x_2 + x_3^\sigma x_4 + K_{\sigma, \varepsilon}$ for every vector $(x_1, x_2, x_3, x_4) \in \tilde{V}$.

In case (1) we have as many isomorphism classes of projective embeddings as the cosets of $\text{PTL}(2, K)$ in the group of all permutations of the set $\text{PG}(1, K)$. In case (2) only two isomorphism classes of projective embeddings exist. In either case, all projective embeddings of S are dominant.
